

THE SANATORIUM

AND THE

TREATMENT OF PULMONARY TUBERCULOSIS

THE QUESTION CONSIDERED IN ITS THERAPEUTICAL AND ECONOMIC ASPECTS

INTRODUCTION.

sent recently to a group of recognised authorities the treatment of pulmonary tuberculosis the following are of the points on which the medical profession, through that profession the public, require early treatment:—

Medical officers of health are constantly asked to advise as to the neighbourhood would be benefited by the erection of a sanatorium for pulmonary tuberculosis, and medical men are similarly consulted either as to the suitability of a certain patient for such a sanatorium or the advisability of subscribing to a fund for providing one in the neighbourhood. On these points they find it difficult to reply which is backed by solid medical opinion.

Unpublishing answers from medical men whom both the lay and lay world know as authorities to the few questions we hope to furnish answers which will be of the time being very valuable. We quite understand that finite answers cannot yet be given upon many important points and that we have left many issues untouched, of which we hope that you will give us information.

Experience demonstrated the therapeutic value of sanatorium treatment generally?

Successful results obtained equally (a) in well-to-do; (b) in the working classes?

For the working classes must an elaborate system of treatment be combined; and are convalescent homes sufficient to prolong the treatment?

What are the arguments for believing that the social value of sanatoriums will be great and wide-spread?

Sanatoriums are considered by some people as places where severe cases may be segregated and by others as where incipient cases may be cured. Ought there to be separate buildings?

It is a medical officer to say when he is asked by a county authority or a private philanthropist is it best for the tuberculous by building a costly sanatorium?

What we had only touched upon certain aspects of this enormous large subject in putting these questions to our collaborators, and we did not desire to pin any one to the task of answering according to category. As seen by the essays which follow, the various

writers have taken their own line in reply, and we are sure that we anticipate the verdict of our readers in saying that an extremely valuable collective opinion is the result.

THE THERAPEUTIC VALUE OF THE TREATMENT OF CONSUMPTION ON SANATORIUM LINES.

BY SIR RICHARD DOUGLAS POWELL, BART., K.C.V.O.,
M.D. LOND.,

PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON;
PHYSICIAN EXTRAORDINARY TO THE KING; CONSULTING PHYSICIAN
TO THE MIDDLESEX, DROMPTON, VENTNOR CONSUMPTION,
AND ST. MARK'S HOSPITALS

I HAVE no doubt whatever of the therapeutic value of the treatment of consumption on sanatorium lines which need not necessarily be carried out in sanatoriums. It supplies the hygienic conditions upon which all therapeutic measures must be based, the keynote of the treatment being the maintenance of the patient in an aseptic atmosphere and the provision of all hygienic measures of feeding, rest, and exercise adapted to his case which are calculated to raise his vital resistance to the highest pitch attainable. Whilst there is room for much advance upon sanatorium treatment there is none for retrogression from it. It has been led up to gradually as experience of the advantages of fresh-air conditions has grown and it may now be regarded as firmly established. Indeed, the principle has concurrently and irrevocably grown to be recognised as the basis of treatment not only for consumption but for all diseases.

The employment of sanatoriums in the treatment of phthisis is now recognised as essential for the great majority of cases, for the reason that few people even amongst those who are fairly well to do can command those conditions of locality, house facilities, garden space, nursing help, and medical supervision which are the important elements of the treatment. And even amongst the more favoured minority there are some who, having country houses with suitable aspects and other requirements, yet find the family conditions of life and temperament incompatible with restful home treatment. As regards the working-classes, so ostracised has consumption become by our hospitals, institutions, and convalescent homes that there is no alternative between the workman's own home or the scanty special hospital accommodation that exists and treatment in sanatoriums. And, indeed, the sanatorium, the ideal place for the treatment of the poor suffering from consumption provided the cases can be properly selected, can scarcely yet be said to have been fairly started for them in this country. It is, then, difficult yet to compare experience with regard to the results of treatment in the industrial cases with those of the upper

and middle classes; and there is the large class of office workers and shop attendants for whom there is little, if any, accommodation at all in the way of efficient sanatoriums.

In the organisation of sanatoriums for the industrial classes—and the point should not be forgotten with all classes—the demoralising effect of six months' idleness which is apparent in most cases after a "rest cure" must be taken into careful account. This can, and must be in some measure at least, counteracted by organising exercises in the shape of some kind of industrial work regulated to the powers of each individual. An attempt in this direction is being made with a considerable measure of success at the Brompton Hospital sanatorium at Frimley and will no doubt be alluded to more particularly by some of my colleagues.

The fact must be squarely faced that impossibilities cannot be effected with phthisis in any grade of the social scale. The majority of patients cannot return to the conditions under which they have broken down without the probability of relapse. They must think out, and their friends for them, a new line of life. Convalescent homes are of no use except to carry on the treatment and to give time with more assured health to reorganise the future mode of life. Advisory committees in connexion with charitable organisation bodies may do much in aid of finding, or starting, or advising with regard to new lines of work for those who have attained arrest or recovery under treatment. Many may, through friends or of their own initiative, find conditions under which they may resume work and keep health; others must relapse until the end comes. There are good grounds, however, for taking a sanguine view of the future as regards consumption amongst the poor. If preventive measures are wisely, patiently, and steadily persevered with, the cases for treatment will gradually diminish to numbers manageable for being more permanently dealt with.

The question of any system of insurance being utilised in the treatment of the consumptive industrial classes is a difficult one which I have touched upon elsewhere,¹ but as I take it that the object of these articles is to elicit opinions warranted by personal experience I will not dwell upon the subject here. Considering, however, the enormous expense to the rates involved by tuberculous disease, the large demands through it upon benefit societies, the great cost of it from mortality-claims to industrial assurance societies,² and the strain it involves upon charitable organisations, it can scarcely be doubted that a combination of funds from such sources might be advantageously arranged towards securing conditions for a diminished death-rate and increased longevity.

Cases of consumption must be classified into those suitable for homes, hospitals, and sanatoriums. The sanitary conditions for each class must, of course, be, so far as practicable, on equally good lines, but it is absolute cruelty to send some cases to sanatoriums as now constituted, whilst it is equally unjustifiable to keep others out. Homes or comfortable asylum conditions are required for advanced cases where symptoms may be treated and their last days made comfortable and happy. It is not enough, however, to relegate advanced cases of consumption to infirmaries or homes for the dying with a view rather to their removal from a sphere of harmfulness to others than for their own advantage and efficient treatment. These poor people should be provided for in hospitals and homes under conditions and with full medical treatment adapted to their cases. Not a few apparently hopeless cases make surprising rallies and

acquire complete quiescence. Such cases, abandoned perhaps by orthodox practitioners, make the reputations of quacks who lucratively abide the processes of Nature's surprising recuperative powers. But for those who are doomed to continue a downward course watchful medical treatment and nursing care can infinitely allay their discomforts and sufferings. They require at our hands at least as much consideration as the more promising cases, and a percentage of beds should be provided for them at each special hospital and at each general hospital in order that nurses and students may learn how to treat them. Bacteriological observation does not justify the view that advanced cases with copious expectoration are attended with more danger from infection than earlier cases. Sputum examinations would warrant a contrary view.

Hospital management is again necessary for cases under diagnosis in acute stages or complications requiring close observation, nursing, and special medical or surgical treatment. For incipient and localised disease and for cases, many of which have passed through a short period of treatment in hospitals or in their own homes, the sanatorium treatment is best adapted. With the complete establishment of sanatorium treatment there are other therapeutic measures yet to be adopted, some of which have not yet been fully if at all evolved, such as the various uses of the creosote class of drugs, regulated tuberculin injections, organised hygienic exercises, and other measures.

There is an unfortunate, and, I am convinced, an exaggerated, belief in the person to person infectiousness of phthisis which is growing under the advocacy of sanitarian and antituberculosis societies. Admitting most of the preliminary data as to the origin of the disease by bacillary infection, the certainty of producing it in a large proportion of cases under experimental conditions of spraying with tuberculous sputum, and the concentrated prevalence of the disease under conditions of overcrowding and insanitation, I am still totally unable from my experience as a physician to endorse the view of tuberculosis being more than rarely acquired directly by one person from another. Were it so the aggregation of consumptive patients in sanatoriums or hospitals would be quite unjustifiable. And it is under this growing belief of such kind of infectiousness that it is already becoming very difficult to induce intelligent people to submit to treatment in sanatoriums. The reverse is the truth, however; patients with consumption are far safer in sanatoriums or hospitals than in their own homes. Medical men and servants administer sanatoriums with impunity. And why? The question would be unanswerable in accordance with the now too prevalent view of the direct infectiousness of tubercle. The reconciliation of the two views is, I am convinced, to be found in the fact that the tuberculous infection is, except under experimental conditions, rather a distributed one than direct from person to person. It is from the insanitary surroundings of patients rather than from patients themselves that infection is acquired. "It is in darkness and filth that tubercle flourishes."³ As with the poison of most other acute specific infectious diseases, the tubercle bacillus is greatly increased in virulence when mingled with other dirt and dust microbes; under clean and sanitary conditions it is not to be feared.

With regard to the final question as to the value of costly sanatoriums, I can only say that the more cheaply we can get our results the better. With ample ground space and for the treatment of incipient or convalescent cases the hut system may be the best. For considerable numbers, perhaps exceeding 20, the sanitation, administration, and supervision become under this system difficult and costly; with really large numbers, exceedingly

100, I should say impossible: large institutions with central administration become necessary. The provision of a cottage sanatorium of, say, four beds for each group of three or four villages in country districts, with a few, perhaps half a dozen or a dozen, beds, with special hygienic provisions in the local infirmaries for advanced cases, would probably be economical and of great advantage in educating local medical men and keeping up their interest in the treatment of consumption. Consulting medical aid and supervision could be easily arranged for from the county towns. In this way the sanatorium treatment of the disease might with great advantage be distributed and cases recognised and treated in earlier stages. But there would still remain the need for larger sanatoriums in connexion with the big towns.

Wimpole-street, W.

THE SANATORIUM TREATMENT OF PULMONARY TUBERCULOSIS.

By SIR WILLIAM H. BROADBENT, BART., K.C.V.O.,
M.D. LOND., F.R.C.P. LOND.,
CONSULTING PHYSICIAN TO ST. MART'S HOSPITAL.

1. THERE can be no doubt as to the therapeutic value of sanatorium treatment. It has been exemplified in many cases which have come under my observation. Everything depends, however, on the skill and care with which the treatment is adjusted to individual cases; something also on situation and climatic advantages.

2. I have no personal experience of the results in the working classes, but the sanatorium experience of Germany, which is very favourable, relates to the industrial classes. In this country working men do not come under observation and enter sanatoriums at an early stage and can rarely remain under treatment long enough. While in the sanatorium they improve rapidly.

3. In order that working men may be induced to enter a sanatorium early and to remain for a sufficient length of time, it is obviously necessary that some provision should be made for the maintenance of the family. Rather than see his wife and children starve, a man will keep at his work as long as possible and return to it as soon as possible, regardless of the consequences to himself. How such provision is to be secured is a difficult question. The organisation of the working classes in this country is not such as to lend itself to compulsory insurance.

3a. It is not so much convalescent homes as industrial colonies that are needed after sanatorium treatment. The sanatorium is a sort of convalescent home itself. In one sanatorium in America the patient is only admitted on condition that he does such work as is ordered and undertakes to remain till he is considered fit to return to his own avocation. Permission to leave is only given when he can do a full day's work without rise of temperature.

4. It has always been the practice in a well-conducted sanatorium to impress upon the patients the importance of free ventilation night and day, of suitable feeding, of destruction of expectoration, and in a large proportion of the cases these instructions are to some extent carried out on their return home.

5. Sanatoriums serve two perfectly distinct purposes—the arrest of the disease in early cases and the prevention of its spread by advanced cases. This difference ought to be recognised. The isolation of advanced cases and, when this is impracticable, their removal from dwellings and surroundings in which they are foci for dissemination of the disease is necessary for the protection of the public, and is as much a matter of public health as the prevention of contamination of drinking water by enteric stools. It is a duty of health authorities everywhere and ought not to be left to charity.

6. A sanatorium provided by a county or other public authority, or by public contributions, ought to be of the simplest possible character. A private philanthropist may be allowed to choose what form his sanatorium takes on condition that he endows as well as erects it.

Brook-street, W.

ON THE OBJECTS AND LIMITATIONS OF SANATORIUMS FOR CONSUMPTIVES.

By C. THEODORE WILLIAMS, M.D. OXON.,
F.R.C.P. LOND.,

CONSULTING PHYSICIAN TO THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON.

THE invitation of the Editors of THE LANCET to discuss certain important questions with regard to sanatoriums about which there is a difference of opinion is a good one if such discussion evokes the matured experience of physicians, but I have written so much and so recently on sanatoriums that I hesitate to inflict on the readers of THE LANCET another communication,¹ however short.

The question has been asked if experience has demonstrated the therapeutic value of sanatorium treatment generally, and the answer of most of us is in the affirmative. No sensible physician ever expected that a few months' stay in a sanatorium would work such changes in the system of a consumptive as not only to arrest his disease but also to render him immune against all future attacks of the tubercle bacillus when he returned to the conditions under which the disease was engendered. Too great expectations were held out of the probable benefits of sanatoriums in this country by those who had had little or no practical experience of consumption and knew not what a serious and insidious disease it really is, and though a warning-note was uttered by myself and others against such wild expectations they were encouraged by the daily press and led to grievous disappointment.

Sanatoriums are intended for cases of consumption of recent origin and with limited lesions with little or no fever. Such patients under the system of a well-organised and well-equipped sanatorium in a good climate gain weight, colour, and probably muscular power, and show diminution, if not disappearance, of cough and expectoration and of tubercle bacilli. The physical signs are lessened and sometimes disappear, arrest of the disease takes place and these patients are said to be cured. But, alas, experience frequently proves this hope to be fallacious, as there is some danger of relapse even in the most promising cases if they return to unfavourable surroundings. Sanatoriums are not intended for advanced cases or even for patients where the lesions are moderate but show signs of extension and of breaking down and are accompanied by pyrexia. They are not places where severe cases ought to be segregated, for this is the function of consumption hospitals where severe cases of all kinds can be properly studied and treated with appropriate nursing, medicines, and food. Hospitals are as necessary in the treatment of consumption as sanatoriums and this is recognised in all countries which attempt intelligently to deal with tuberculosis as a whole. Such are Sweden and Denmark, for these, while distributing magnificent sanatoriums over the country on the best-chosen sites, also build well-equipped consumption hospitals near Copenhagen and Stockholm.

Where this division is not carried out, as I have witnessed on more than one occasion, the results are disastrous, for the sanatorium becomes choked with patients with advanced disease, for the most part bed-ridden and on their road to the grave, and what chance could promising cases have in

¹ THE LANCET, Jan. 30th, 1904.

such company? The Brompton Hospital has long recognised these objects, though circumstances prevented their realisation till lately. Now, in addition to the parent hospital, they have established an excellent sanatorium of 100 beds at Frimley for incipient tuberculous cases and by a most careful selection of patients, which the skilled diagnosis of their accomplished acting staff renders possible, the beds are filled with suitable cases. The results, as far as they go, are satisfactory and will in due time be published by the committee of management. The North London Hospital for Consumption has taken a similar course.

For the treatment of consumption three institutions are required: (1) a consumption hospital to deal with all acute and advanced cases; (2) a sanatorium for patients with incipient and limited lesions, for the most part able to take exercise; and (3) a settlement or colony of patients with arrested consumption where these can be employed on work adapted to their strength and capabilities. In the United States, especially in the Western States, a goodly number of the patients are to be found following outdoor occupations and proving themselves useful members of society. If the patients be retained at the sanatoriums, as they ought to be until the disease is arrested or, at any rate, quiescent, any further convalescent homes are unnecessary, for they should be transferred at once either to the proposed settlement or to their own homes to carry out there the hygienic life in the principles of which they have been trained.

With regard to the proposal of combining a system of insurance with the sanatorium movement, as has been done in Germany, I for one should welcome such a plan, but I doubt whether the British working man would support it less he is compelled to do so by the State, as is the case in Germany under Bismarck's famous law for compulsory insurance of workmen against industrial accidents and sickness.

The question whether successful results are obtained equally in the well-to-do and the working classes in sanatoriums I should answer in the negative. As far as my experience goes the consumptives of the upper classes have more recuperative power than those of the working and lower classes and this comes out in sanatorial as well as in other forms of treatment. When I used to compare my hospital and private patients I often noticed that in a number of cases of tuberculous consolidation at one or both apices excavation took place much more rapidly among the poorer or hospital patients than among the well-to-do, and the same was the case with regard to extension of disease. Nevertheless, the working classes do make great progress towards recovery under suitable conditions. Fresh air and good food do wonders for them and they gain flesh and strength; but the improvement in the physical signs appears to me slower than in the well-to-do. It remains to be seen what the system of graduated labour introduced at the Frimley Sanatorium will do for the patients of the poorer classes and my impression is that it will put them more on a par with the well-to-do who owe so much to graduated exercise.

The educational value of the sanatorium cannot be questioned and as the patients return to their homes it will become more and more widespread. The consumptive who has been an inmate of a well-organised sanatorium, having been trained to deal with his sputum and other secretions is no longer a source of danger to his neighbours and returns to his family the ardent apostle of fresh air and of wholesome living and the strong opponent of dirt, dust, uncleanness in any form, want of ventilation, and overcrowding. Such an apostle, though sometimes trying in a household where there are aged inmates or those suffering from rheumatism or bronchitis, does incalculable good in the dwellings of the poor and enforces his gospel by example as well as by precept. At the Brompton Hospital, which is

now completely under the open-air system, many consumptives sit by preference by the open windows instead of crowding, as formerly, round the fires.

With regard to the reply of the medical officer when consulted by the county authority or philanthropist "whether they are doing their best for the tuberculous in building a costly sanatorium," I, objecting strongly to the word *costly*, would recommend him to advise the building of a hospital or sanatorium of some kind in the interests both of the community and of the patient. Cases of acute or advanced consumption with expectoration abounding in tubercle bacilli are more or less infectious and are therefore a danger to those around them. These cases ought to be segregated in a hospital where they can be properly attended to and disinfection carried out. Cases with slight or quiescent lesions require more fresh air and better food than is usually to be obtained in the dwellings of the poor. The great objection to all hospitals and sanatoriums is their cost, which in the best German and English institutions has been considerable, and which for the most perfectly constructed and equipped will always remain high. But we might provide some of our Poor-law infirmaries with buildings of a cheaper and perhaps more temporary kind if only the British architect would devote his energies to this practical problem and tackle the many difficulties which surround it. We must, however, remember that after all the great aim of statesmen, philanthropists, public authorities, and medical men ought to be the *prevention* of tuberculosis rather than its *cure*, and this can only be attained by the removal of all the conditions which deteriorate the constitutional powers and predispose the individual to the bacillar attack.

When we have abolished the evils of overcrowding, of excessive hours of work in an unwholesome atmosphere, and of insufficient food, and have secured the wholesome homes and workshops for the poor, contemplated by Acts of Parliament and by County Council regulations, when we have checked drunkenness and vice and have made sure that our population are properly fed and clothed, we shall be approaching the looked-for result—the prevention of tuberculosis.

Upper Brook-street, W.

THE THERAPEUTIC VALUE OF SANATORIUM TREATMENT IN PULMONARY TUBERCULOSIS.

By J. KINGSTON FOWLER, M.A., M.D. CANTAB.,
F.R.C.P. LOND.,

CONSULTING PHYSICIAN TO THE BROMPTON HOSPITAL FOR CONSUMPTION; SENIOR PHYSICIAN TO THE MIDDLESEX HOSPITAL;
DEAN OF THE FACULTY OF MEDICINE, UNIVERSITY OF LONDON.

In a paper¹ read before the Royal Medical and Chirurgical Society on Nov. 14th, 1899, as an introduction to a discussion on the Open-air Treatment of Tuberculosis, I stated my conclusions² as follows:—

"It is hardly necessary to state that in not all the cases treated on this system does arrest of the disease follow. The test to be applied to any method is not, Will it cure every case? but, Is it the best with which we are acquainted? If a perfectly certain cure for tuberculosis were discovered to-morrow it would necessarily have limits to its application and a very large number of existing cases would certainly be beyond those limits. In this, as in all other affections, the sooner the patient is brought under treatment the greater is the chance of the disease undergoing arrest. It is, however, a mistake to suppose that it is a method only applicable at a very early period of the disease. The experience of the

¹ Transactions of the Royal Medical and Chirurgical Society, vol. lxxxiii., p. 1.

Loc. cit., p. 24.

last ten years at Nordrach is conclusive as to the good effects which may in some cases be expected, even when the area of the lungs affected is considerable and excavation has taken place. On one point, at least, I am fully convinced—viz., that if Brehmer's method can be successfully applied in this country, as I have every reason to believe will be the case, we should take Nordrach as our model in preference to any other existing sanatorium. Those whose experience extends so far back even as 20 or 25 years have seen many methods of treating this disease put forward, supported in some cases by names of authority, and in nearly all by statistics of gratifying success already obtained. They come, they have their day, and go and are forgotten. Is this method, call it by what name you will, but another which will share the same fate? I think not; I believe that it has come to stay. No one can tell what the future has in store in the field of therapeutics and it is by no means improbable that the next century may witness the discovery of some agent capable either of conferring immunity to the virus of tubercle or of arresting the extension of tuberculous lesions, but a system which aims at increasing by every means the resisting power of the body must, I believe, always find a place amongst the methods to be employed in combating tuberculosis of the lungs."

During the six years that have since elapsed I have had considerable further opportunities of observing the effects of sanatorium treatment and am glad to be able to state that the opinion I expressed in 1899 as to the great value of this method of treatment as carried out by Dr. Otto Walther at Nordrach has been in no degree altered; I am still convinced that it is "the best with which we are acquainted." I am glad to observe that you use in the communication which you have forwarded to me the term "sanatorium treatment"; it is one the adoption of which I advocated in my paper. As I there stated,¹ "the object of treatment is not merely to secure the arrest of the disease but those changes in the affected area which characterise obsolete lesions. It is important to remember that for such changes to take place a long period of time is required, to be measured in some cases by years, and that failing this it is very likely that the patient will suffer a relapse so soon as he submits to the strain which a busy life entails." Disappointment has resulted because this fact has not been recognised and relapses have been frequent. The treatment produces such an unwonted feeling of health that patients, no matter how carefully they have been advised, at times forget the necessity for such a prolonged period of care. The experience of Dr. Walther led him to formulate the rule that for two years subsequent to "arrest" the patient should avoid any violent exercise and my own experience has proved the wisdom of such advice. In nearly all the cases of relapse which I have observed the breakdown has been due, not to the work of life, but to over-exertion, either in sport or games. I regard this as the chief danger which confronts the well-to-do patient. Fortunately, in most cases a return for a few months to sanatorium life has sufficed to arrest again the activity of the disease.

THE NORDRACH SYSTEM.

The features which distinguish the Nordrach system are, very briefly:—1. An absolutely open-air life, day and night, in sunshine, fog, or rain. 2. No *liegehalte*. 3. An abundant diet, regulated by the judgment of the physician in charge, who must attend at all the meals. 4. Rest before meals. 5. Exercise regulated according to the bodily temperature and strength of the patient.

The form of exercise held by Brehmer to be most suitable for cases of pulmonary tuberculosis was slow up-hill walking. One of the reasons for the great success obtained at

Nordrach is that the site is admirably suited to this form of exercise. In the paper already referred to I stated (p. 17): "It is very desirable that correct views should prevail upon the place which exercise occupies as an integral part of this method. Many members of the profession and the public appear to have grasped two facts in connexion with it, but this is not one of them. Such may be again reminded that a patient may lie in the open air till 'all's blue,' including, as I have observed, his cheeks, and be stuffed with food till he is as fat as a Strassburg goose, and yet the disease in his lungs may not be arrested. Brehmer's method, when properly carried out, is a system of training which aims at developing in every possible way the bodily strength, and for this exercise is as necessary as fresh air and plenty of food." The longest walk taken by patients at Nordrach is about 24 miles in the day. In the course of the discussion one of the speakers stated that the Germans had been unable to find Nordrach. In my reply I ventured to express the opinion that "if they had found Nordrach and lost nearly all the other sanatoria it would have been the better for them." Information derived from a friend who has quite recently visited Berlin and some sanatoriums in Germany leads me to think that Nordrach has not yet been found—indeed, he was told by a high official that they "do not know anything of Nordrach."

Since 1899 several efficient and many inefficient sanatoriums have been established in this country and from personal experience I feel able to state that only those that have taken Nordrach as their model have proved to be worthy of the support of the profession.

THE BROMPTON HOSPITAL SANATORIUM.

I am well acquainted with, and had some share in establishing, the Brompton Hospital Sanatorium at Frimley, which was opened for the reception of patients in March, 1905, and I would invite any of your readers who are troubled with doubts as to the value of sanatorium treatment in tuberculosis of the lungs to pay a visit there. I should like to take this opportunity of expressing my high opinion of the admirable organisation and discipline which Dr. M. S. Paterson, the medical superintendent, has instituted, as it is entirely to his efforts that the success so far obtained has been due.

Each batch of patients on arrival from the parent hospital at Brompton—through which they must all pass—is addressed by the medical superintendent on (1) discipline, (2) fresh air, and (3) feeding. As they have already been trained at Brompton for the lesson they have to learn they find but little difficulty in falling in with the more complete open-air life followed at Frimley. It was, however, not an easy task to establish the tradition of absolute obedience to orders which now prevails; the conviction as to the wisdom of the regulations came to the patients as they found themselves steadily improving in health and strength. Now everyone cheerfully goes about his appointed exercise or work irrespective of the weather, and if told off to roll the lawn for two hours he does it and is not found after five minutes sitting upon the handle of the roller.

As an illustration of the thoroughness of the treatment so far as "open-air" is concerned, I may state that the desire of the majority of the patients whose bedrooms on the upper floor are without a balcony is to be promoted to a room with a balcony, or to one on the ground floor, so that they may be able to pull out their beds and sleep in the open air. I was told when at Frimley in December, 1905, that most of the patients at that time slept in the open air when it was not raining. During the recent frosty weather the patients were told that they could close their windows for an hour whilst they were dressing, but it was found that none of the windows were closed. Hats and caps are not worn except when walking outside the grounds.

¹ Loc. cit., p. 8.

The appetite developed by an open air life is surprising; as most of the staff voluntarily lead the same life they experience a similar increase of appetite.

Daily routine.—6.50 A.M.: Rise and turn down beds and proceed according to "Morning Routine." 8.15 A.M.: Breakfast for tables 1, 2, and 3. 8.30 A.M.: Breakfast for tables 4, 5, and 6. 9.30 to 9.55 A.M.: Indoor work. 10 A.M.: Outdoor work or exercise. 10.50 A.M.: Lunch. 11 A.M.: Outdoor work or exercise. 12 to 12.45 P.M.: Absolute rest for tables 1, 2, and 3. 12 to 1 P.M.: Absolute rest for tables 4, 5, and 6. 1 P.M.: Dinner for tables 1, 2, and 3. 1.15 P.M.: Dinner for tables 4, 5, and 6. 2 to 2.45 P.M.: Absolute rest for tables 1, 2, and 3. 2.15 to 2.45 P.M.: Absolute rest for tables 4, 5, and 6. 2.45 to 4.35 P.M.: Work or exercise in grounds. 5 P.M.: Tea for tables 1, 2, and 3. 5.15 P.M.: Tea for tables 4, 5, and 6. 5.50 P.M.: Temperatures taken for tables 1, 2, and 3. 6.5 P.M.: Temperatures taken for tables 4, 5, and 6. 6 to 7.45 P.M.: Read papers, write letters, play indoor games, &c. 7.45 P.M.: Supper for tables 1, 2, and 3. 8 P.M.: Supper for tables 4, 5, and 6. 8.40 P.M.: Prayers. 8.45 P.M.: Bed. 9.15 P.M.: Lights out. 9.30 P.M.: Silence.

A quarter of an hour is allowed for smoking after each meal. A quarter of an hour is allowed before each meal for washing. Patients are not allowed indoors except for meals and rest hours until 6 P.M. without special permission. Patients may use the concert hall and reading room from 6 P.M. until prayers.

Sunday routine.—The routine is the same, with the following differences: There is no work. 9.30 to 10.35 A.M.: Patients walk two miles in all weathers. 11 A.M.: Divine service. 12 noon: Rest hour. 2.30 P.M.: Those patients who have permission may walk outside the sanatorium until 4.45 P.M.

The patient's day is thus so completely occupied that he has little leisure for introspection and I am informed that the only common complaint is "We are kept so busy we have no time for anything."

Graduated labour.—The new feature which Dr. Paterson has introduced at Frimley is graduated labour, a feature which appears to me to go far to solve the question as to the applicability of sanatorium treatment to the poorer classes. County authorities and the public are naturally asking: "Are the patients whom you call 'cured' able to work and earn their own living?" (I deprecate the use of the word "cure" but the public will have it so.) Upon the answer which we are able to give to this question the provision of adequate sanatorium accommodation for the poor depends. I believe we can state that the patients classed as "arrested" after treatment at Frimley are fit for work.

The gradation of exercise and labour is as follows:—Exercise and labour are for two periods daily, each of two hours' duration. 1. Slow walking exercise, beginning at two miles a day and gradually increasing up to ten miles a day. 2. Picking up fir cones and firewood in the grounds and carrying a "half-basket" (weight 11 pounds) to the stack. 3. Carrying a full basket of firewood and cones (weight 16 pounds). 4. Carrying a "half-basket" of gravel or stones from the gravel pit to the place where paths are being made or repaired (weight 21 pounds). 5. Carrying a basket of gravel or stones, the weight of which is gradually increased up to 38 pounds. 6. Rolling the grass or gravel. 16 men pull a roller weighing 15 cwt. 7. Digging ground already broken. 8. Mowing grass with a lawn mower. 9. Digging unbroken ground. 10. The same as under 9 but for six hours daily instead of four hours—i.e., the hours usually spent at rest are spent in labour.

The indications accepted as evidence of the arrest of the disease are: (1) absence of fever; (2) absence of adventitious sounds, except such as are indicative of

fibrosis; (3) absence of cough and expectoration; (4) continuous gain of weight or maintenance of the patient's highest known weight; and (5) ability to perform labour incidental to grade No. 9 as above.

The point to which I wish especially to draw attention is that no patient is classified on discharge as "arrested" unless for three weeks continuously he can pass one or other of the following tests:—

Test A.—For patients who earn their living by manual labour: To be able on an ordinary diet and without rest hours to use a pick and shovel of the full size and weight for six hours daily and to maintain his health. The shovel and spades are in three sizes, weighing 2, 4, and 6 pounds respectively. The picks vary from 3 to 7 pounds in weight.

Test B.—For patients who do not earn their living by manual labour, e.g., clerks, shopmen, or salesmen: To be able on an ordinary diet to perform the labour of grade No. 6 or No. 7 for six hours daily for three weeks and to maintain his health. These patients are, as a rule, gradually brought up to No. 9 and when it is found that they can do this work they are put back to No. 6 or No. 7. The theory is that a man doing the work described under No. 9 or No. 10 who on discharge will engage in work involving but little bodily exercise would suffer in health from such an abrupt transition. Further experience is, however, necessary upon this point. In some cases it is found that patients are unfit for No. 9 but that they can be raised to a standard of labour which is equal to their ordinary work. These patients are tested before discharge on the grade to which they have attained but they are not, as a rule, classified as "arrested."

The system has been gradually evolved and has not yet been in operation for a sufficient time to justify the expression of a final opinion as to its value, but there appears to be every reason for anticipating that it will prove successful. A visit to the sanatorium will convince anyone of the healthy, not to say robust, appearance of the patients on graduated labour. I am told that the desire of every patient on walking exercise is to be allowed to work; that the man engaged in collecting wood envies the man who is carrying gravel; that a patient with a large pick-axe is regarded as a fortunate being by his neighbour with a small one; and that, in a word, there is a general desire to obtain promotion to a higher grade of labour. So marked is this feeling that experience has shown that constant supervision and surprise visits are necessary, not, as might have been anticipated, to ascertain that the patients are doing their work, but to see that they are not exceeding the amount of work they are fit for.

The sanatorium is fortunate in having a public gravel pit on a breezy site close by where any amount of work may be done, and it is found that if a patient at work in the grounds is not making progress he is very likely to do so if sent to dig in the gravel pit. It should not prove difficult to adapt this scheme of graduated labour to the local features of any sanatorium provided that a sufficient area of land is either purchased or rented, and I see no reason why it should not prove equally applicable to sanatoriums for private patients. If it were explained to such patients that manual labour was an essential feature of the treatment I believe that few would refuse to perform it.

Long before the existence of a sanatorium in this country I was in the habit of sending patients to work in horticultural gardens and the good results which followed convinced me of the value of light labour in the open air. I believe that the ideal to aim at is to surround every sanatorium with such a garden, as no open-air occupation presents such a variety of grades of labour as is to be found in a horticultural garden.

Results.—The results so far obtained at the Brompton

sanatorium are as follows: patients admitted, 190; discharged, 89; under treatment, 101.

Cases discharged.—Disease arrested, 23; disease probably arrested, 4; left at own wish, 30; discharged as unsuitable, 16; convalescent cases,⁴ 16; total, 89.

Patients send reports as to their health and occupation at intervals of three months after discharge. All the patients classed as "arrested" are known to be at work and earning their living, except such as have not sent the first report—i.e., a shorter period than three months has elapsed since their discharge. The 30 patients who left at their own wish did so for the following reasons: family reasons (e.g., wife out of work, wife in bad health, stoppage of club pay to wife), 19; "felt quite well and did not see the necessity for further treatment,"⁵ 8; fear of losing their work, 2; because a patient was found smoking out of hours and in the woods and was discharged and he had been smoking with discharged patient but was not discovered, 1; total, 30. 16 patients were discharged as not suitable: disease so extensive that it was impossible for patients to work without rise of temperature or because suffering from dyspnoea, 11; coming home drunk, 1; smoking in the woods, 1; mentally deficient, 2; suffering from asthma, 1; total 16.

CONCLUSIONS.

My answer, therefore, to your first question is: That "experience has demonstrated the therapeutic value of sanatorium treatment" provided it is carried out on the right lines. To your second question I reply that, with the same proviso, "the results obtained may be equally successful with well-to-do patients and with the working classes." As to the necessity for "an elaborate system of insurance for the working classes," it may be stated that at Frimley nearly all the male patients who have broken down whilst in employment and have been valuable to their employers are found to be in receipt of full pay for six months. This is very kindly action upon the part of the employers and their generosity is much to be commended. The limits of this paper prevent me from discussing the general question of the possibility or desirability of adopting the system of industrial assurance as carried out in Germany. If we are able to obtain results which carry conviction as to the value of this method of treatment as applied to the poor then my belief is that, given a reasonable prospect of a patient being restored to a state of health which will enable him to earn his living, the money necessary for the support for six months of any who may be dependent upon him will generally be forthcoming from some charitable source.

Provided the treatment in the sanatoriums for the poor follows the lines above described, and the patient before his discharge is able to stand the labour test which immediately precedes it, there should be no "necessity for convalescent homes to prolong the treatment." I believe, however, that if the co-operation of the managers of convalescent homes throughout the country can be obtained these institutions, if utilised in a manner to be presently described, may be of great service in dealing with this disease.

The best answer I can give to your other questions is to state briefly the lines of policy which should, in my opinion, be followed in dealing with pulmonary tuberculosis throughout the country.

GENERAL SCHEME.

1. Every general hospital and every special hospital for diseases of the chest should be in relation with a sanatorium.
2. Every general hospital and every special hospital for diseases of the chest should have a tuberculosis department.

⁴ A certain number of beds are reserved for "convalescents" who are not undergoing sanatorium treatment.

⁵ Letters to patients now in the sanatorium show that several of these cases have relapsed.

This might be, but would not necessarily be, a separate clinique, but would be a bureau of registration with an almoner attached.

3. A register should be kept of all patients suffering from pulmonary and other forms of tuberculosis and the patients should be classified under the following headings: (a) suitable for sanatorium treatment; (b) suitable for general or special hospital or for home treatment; and (c) suitable for Poor-law infirmary treatment.

4. The department should supply a leaflet giving instructions to patients as to the proper method of dealing with the sputum and also provide them without charge with a portable spittoon and the necessary disinfecting solution.

5. It would be the duty of the almoner to visit the homes of the patients in order to ascertain if other inmates were already infected and by kindly persuasion and advice to induce them to submit to treatment and to take the necessary measures for preventing the further spread of infection.

6. Pending the acceptance of compulsory notification of tuberculosis the general hospitals throughout the country and such other agencies as could be enlisted in the work should collect information as to the existence of centres of infection and thus help to check the spread of the disease.

7. No effort should be spared to secure the admission to sanatoriums of patients in the early stage of the disease, in which stage alone in dealing with the poor is it likely that economic results—i.e., complete arrest with ability to work—will be obtained.

8. The cases must be selected by competent medical men. If admission to the sanatoriums is governed by any system of nomination or of subscribers' letters my belief is that the suitable cases will not be obtained and the scheme will fail.

9. The general and special hospitals should be in relation with convalescent homes in which a certain number of beds should be set apart for patients, possibly, but not certainly, suffering from tuberculosis. Whilst in the home these patients should be treated on sanatorium lines and such as develop the disease should be transferred to a sanatorium as opportunity offers.

10. The newly established Convalescent Homes Association has here a great opportunity for proving its usefulness. If it can obtain this much-needed co-operation between the hospitals and the homes it will have fully justified the efforts of its founders and will have performed a most useful work.

Clarges street, W.

THE SANATORIUM TREATMENT OF PULMONARY TUBERCULOSIS.

By FRANK J. WETHERED, M.D. LOND., F.R.O.P. LOND.,

PHYSICIAN TO THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON; ASSISTANT PHYSICIAN TO THE MIDDLESEX HOSPITAL.

IN attempting to arrive at a definite opinion as to the value of the sanatorium treatment of pulmonary tuberculosis numerous difficulties are met with. The statistical evidence now to hand is in some respects contradictory but on the whole decidedly encouraging. The contradictions are, perhaps, more apparent than real and arise in devious ways. One fact that causes confusion is that the authorities in charge of some sanatoriums admit patients in all stages of the disease, whilst others only take cases in the early stages. Thus the results are much more favourable in the latter institutions than in the former. It must be noted also that many of the figures that have been published through various channels refer only to the results achieved when the patients leave the sanatorium, whereas it is evident that that is not the crucial point, the essence of the whole matter being how the patients progress during subsequent years. As an illustration of the false impressions that might arise owing to the want of uniformity in the

sease has passed beyond the stage when the chances of cure are highest. He dates his illness not from the commencement of the symptoms but from the time when he has to give up work. Even if the patient should come under medical observation when there is only slight infiltration in the lung and consents to undergo suitable treatment, if he or she be married, the thought of "home" and those dependent on their labour and care is constantly present and a natural source of worry and anxiety. Consequently, if no improvement be manifested after a few weeks, the man is troubled with the idea that his wife and family are suffering from his absence from work and the loss of the income derived therefrom, and he insists upon returning to work when the reparative processes have only just begun, with the almost certain consequence—a relapse. The woman acts in a similar manner and against all advice returns home to her children and deplorable results ensue. Not only does she herself rapidly become worse, but there is a possibility of her infecting others. These considerations naturally weigh less if the patient is unmarried and has no one dependent upon him or her. A longer stay in the sanatorium is then possible and a prospect of arrest of the disease more hopeful. But even if the first two conditions are fulfilled—an early diagnosis and six months' residence in the sanatorium can be carried out—all the benefits thereby attained may be ultimately set at naught by the patient returning to unhealthy surroundings and an unsuitable occupation. A man accustomed to outdoor life may be able to continue to pursue the course of life he has been taught whilst under active treatment. But what is a man who has been brought up as a clerk, a lithographer, a baker, or a tailor to do if he cannot return to his former means of earning a living? Such men know nothing of a country life and yet if they return to their former occupations relapse is most probable. Yet how, with the necessary change of work, can they hope to earn sufficient money to support themselves and those dependent upon them?

The majority of the patients who entered the sanatorium in the early stage of the disease and remained a sufficient length of time there will probably have been discharged as "greatly improved and fit for work." Other patients will have been sent out as "unfit for work" and advised to "take things as easily as possible." Inquiries into the future of these two classes yield peculiar results. According to statistics at the end of four years about an equal percentage are alive and able to do light work. The explanation is that those who were discharged "fit for work" returned to hard and unsuitable labour and surroundings and many of them speedily relapsed, whilst those "unfit for work" led quieter and more sheltered lives, capable, perhaps, of undertaking a little light work, and being carefully looked after by their friends or charitable institutions. They were thus able to drag on through an invalid life and did not suffer from severe recrudescence of active disease.

In the public mind "quiescence" is too frequently confounded with "cure" of the disease. Quiescence or temporary arrest may be brought about within six months under suitable treatment, but two or three years at least are required before "cure" can be pronounced. Here lies the difficulty in inducing patients to appreciate the consequences of "after-treatment" in the shape of suitable employment subsequently to leaving the sanatorium. Sanatoriums for the working classes, if they are to repay the money expended upon them, must be accompanied by farm colonies or other means to instruct the patients in suitable employments. Otherwise the ultimate results can only be disappointing.

This consideration leads to a third question. In the case of working classes, must an elaborate system of insurance

be combined with a system of sanatoriums and are convalescent homes necessary to prolong the treatment? To both these points I unhesitatingly answer "Yes." I consider that the proposed schemes for building such institutions will prove a failure unless insurance against disease is made compulsory. The idea that the institutions should be supported by the funds of trade unions, friendly societies, and kindred associations is excellent, but judging from the speeches made on the subject by those who are not medical men very wrong impressions have been created in their minds as regards the true significance of open-air treatment. The idea seems to have arisen that a person suffering from "consumption" has only to go to a sanatorium for a few weeks—"three months" is the term frequently used—in order to be "cured." Even in the case of highly educated individuals quiescence is mistaken for cure, and assemblies of working men receive with applause the announcement that the speaker has known fortunate individuals who have secured admission into a sanatorium for a few weeks to come out cured. Exaggerated notions are thus excited and the sanatorium treatment comes to be regarded as having an immediate and miraculous effect. Those who are intended to be responsible for the maintenance of these sanatoriums must be made to understand thoroughly the three principles I have already alluded to—early diagnosis, prolonged stay in the sanatorium, and subsequently suitable employment. In order to secure these essentials to the workers, I consider compulsory insurance to be absolutely necessary. A working man will far more willingly seek medical advice if he knows that if prolonged treatment is necessary his family will be supported during his absence. Consequently, instead of struggling on until he can work no longer, being afraid of losing a good situation, as soon as the early symptoms develop, such as cough and loss of weight, he would at once go to a medical practitioner in order to ascertain the nature of the malady. An early diagnosis would thus be much more frequent than in the present circumstances, and so the success of sanatorium treatment would be correspondingly increased. Further, the knowledge that his family would not be in want of the necessities of life would enable the patient to remain the necessary length of time in the sanatorium and so would diminish the risk of relapse. Aid should be forthcoming from the insurance funds to help to support the patient and his family until he could learn some outdoor employment. In such circumstances hopes of permanent cure would be considerably brighter than is possible under the present condition of affairs in this country. The oft-quoted German statistics, especially of the railway workers, demonstrate the advantages that can be gained by imposition of compulsory insurance.

If self-supporting sanatoriums are actually brought into existence one most important point must be insisted upon, and that is, that although the funds will be provided by trade unions and friendly societies, yet the management of details must be vested in the hands of medical men. As I have already several times pointed out, early diagnosis is all-important if success is to follow, and therefore the selection of cases must rest entirely with the medical officers and not with the officials of the supporting societies. For not only must the disease be in an early stage but indications of activity must be absent. The sanatorium will in a certain sense belong to the working men but that must not give them the right to nominate for themselves the patients who are to be admitted. If a worker is found to be suffering from pulmonary tuberculosis in an advanced stage there will naturally be a wish amongst his fellows, kindly disposed as they are, to "give that man a chance" by nominating him to a bed in the sanatorium and to try to insist on his admission. It may seem hard on the individual, and such a course may be deplored, but if the maximum benefit is to be

disease has passed beyond the stage when the chances of cure are highest. He dates his illness not from the commencement of the symptoms but from the time when he has to give up work. Quiescence or temporary arrest may be brought about within six months under suitable treatment, but two or three years at least are required before "cure" can be pronounced. Here lies the difficulty in inducing patients to appreciate the consequences of "after-treatment" in the shape of suitable employment subsequently to leaving the sanatorium. Sanatoriums for the working classes, if they are to repay the money expended upon them, must be accompanied by farm colonies or other means to instruct the patients in suitable employments. Otherwise the ultimate results can only be disappointing.

This consideration leads to a third question. In the case of working classes, must an elaborate system of insurance

be combined with a system of sanatoriums and are convalescent homes necessary to prolong the treatment? To both these points I unhesitatingly answer "Yes." I consider that the proposed schemes for building such institutions will prove a failure unless insurance against disease is made compulsory. The idea that the institutions should be supported by the funds of trade unions, friendly societies, and kindred associations is excellent, but judging from the speeches made on the subject by those who are not medical men very wrong impressions have been created in their minds as regards the true significance of open-air treatment. The idea seems to have arisen that a person suffering from "consumption" has only to go to a sanatorium for a few weeks—"three months" is the term frequently used—in order to be "cured." Even in the case of highly educated individuals quiescence is mistaken for cure, and assemblies of working men receive with applause the announcement that the speaker has known fortunate individuals who have secured admission into a sanatorium for a few weeks to come out cured. Exaggerated notions are thus excited and the sanatorium treatment comes to be regarded as having an immediate and miraculous effect. Those who are intended to be responsible for the maintenance of these sanatoriums must be made to understand thoroughly the three principles I have already alluded to—early diagnosis, prolonged stay in the sanatorium, and subsequently suitable employment. In order to secure these essentials to the workers, I consider compulsory insurance to be absolutely necessary. A working man will far more willingly seek medical advice if he knows that if prolonged treatment is necessary his family will be supported during his absence. Consequently, instead of struggling on until he can work no longer, being afraid of losing a good situation, as soon as the early symptoms develop, such as cough and loss of weight, he would at once go to a medical practitioner in order to ascertain the nature of the malady. An early diagnosis would thus be much more frequent than in the present circumstances, and so the success of sanatorium treatment would be correspondingly increased. Further, the knowledge that his family would not be in want of the necessities of life would enable the patient to remain the necessary length of time in the sanatorium and so would diminish the risk of relapse. Aid should be forthcoming from the insurance funds to help to support the patient and his family until he could learn some outdoor employment. In such circumstances hopes of permanent cure would be considerably brighter than is possible under the present condition of affairs in this country. The oft-quoted German statistics, especially of the railway workers, demonstrate the advantages that can be gained by imposition of compulsory insurance.

If self-supporting sanatoriums are actually brought into existence one most important point must be insisted upon, and that is, that although the funds will be provided by trade unions and friendly societies, yet the management of details must be vested in the hands of medical men. As I have already several times pointed out, early diagnosis is all-important if success is to follow, and therefore the selection of cases must rest entirely with the medical officers and not with the officials of the supporting societies. For not only must the disease be in an early stage but indications of activity must be absent. The sanatorium will in a certain sense belong to the working men but that must not give them the right to nominate for themselves the patients who are to be admitted. If a worker is found to be suffering from pulmonary tuberculosis in an advanced stage there will naturally be a wish amongst his fellows, kindly disposed as they are, to "give that man a chance" by nominating him to a bed in the sanatorium and to try to insist on his admission. It may seem hard on the individual, and such a course may be deplored, but if the maximum benefit is to be

manner in which results are stated I will take the very interesting statistics issued by Dr. Lawrason Brown, resident physician to the Adirondack Cottage Sanatorium, Saranac Lake, N.Y.¹ A summary of results in 1500 cases is given, the patients having been discharged from the institution from two to 18 years previously. In all, 497 (33 per cent.) patients were alive at the time the report was issued; 569 (38 per cent.) were dead and 434 (29 per cent.) could not be traced. Of the 497 patients who were alive 329 (22 per cent.) were "well"; 69 (4·6 per cent.) were "arrested"; 44 (3 per cent.) relapsed; and 55 (3·7 per cent.) were "chronic." Such results do not appear to be satisfactory as they only show 4·6 per cent. of arrested cases and 22 per cent. of patients who were well. Now if the 434 cases in which the patients could not be traced are eliminated the outcome, as Dr. Brown shows, is slightly better. In 1066 cases the patients could be traced; of these 31 per cent. were well; 6·6 per cent. were "arrested" cases; 4 per cent. had relapsed; 5·2 were chronic cases; and 53·3 per cent. had died. If, however, each class of case is considered separately, according to the stage of the disease, very different conclusions can be arrived at. Of the number of incipient cases that could be traced 66 per cent. were well and 21 per cent. were dead. Of the 563 advanced cases which were traced, 28·6 per cent. were well and 52 per cent. were dead; whilst of the 235 far advanced cases 2·5 per cent. were well and 90 per cent. were dead. It is evident, then, that in order that any opinion may be derived from figures all statistical reports must be based on a common plan, otherwise confusion must arise. Further, conclusions based only on a small number of cases are of only very little, if of any, value. Early cases of pul-

monary tuberculosis may heal spontaneously, as is shown by post-mortem experience at general hospitals. If early cases are placed under any sensible treatment a fair percentage will show temporary improvement and it would be very fallacious to base conclusions on a dozen or so cases treated by a new method. For any therapeutic measure to be thoroughly tested the results must be based on a large number of cases which have been observed over a course of years.

under treatment; (2) if the patient remained under active treatment for a sufficiently long period which, in most cases, I consider should be at least six months; and (3) if a healthy outdoor life could be subsequently followed. There may be a few exceptions to the last-named condition, but a return to an indoor and sedentary occupation is accompanied by serious risks of a relapse. I believe the sanatorium treatment of pulmonary tuberculosis to be the best that has hitherto been introduced, but at the same time it is by no means a specific, and only a certain proportion of the patients can hope for partial or complete recovery. Certain adjuvants may from time to time be introduced. In some sanatoriums Koch's old tuberculin is being used and satisfactory results are claimed. Further experience and lapse of time, however, are necessary before any definite pronouncement can be made as to this addition to ordinary sanatorium methods.

Another question asked is: "Are successful results obtained equally (a) in well-to-do patients and (b) in the working classes?" Up to the present I believe not, but I see no reasons why the results should not be equally favourable as I shall presently explain. Owing to circumstances more patients of the well-to-do classes are, under the present conditions of society in this country, able to abide by the three principles I have named above than is the case with those of the working classes. Further, the more independent the patient as regards the necessity of earning a living the better is likely to be the result.

I have to thank Dr. H. G. Felkin for supplying me with the statistics of 100 patients who have been under the care of himself and Dr. R. Mander Smyth at the Linford Sanatorium, Ringwood, New Forest. In the accompanying table the

TABLE OF RESULTS OF TREATMENT AT THE LINFORD SANATORIUM, RINGWOOD, NEW FOREST.

Seven of the patients were lost sight of and one patient died from other causes than pulmonary tuberculosis.

monary tuberculosis may heal spontaneously, as is shown by post-mortem experience at general hospitals. If early cases are placed under any sensible treatment a fair percentage will show temporary improvement and it would be very fallacious to base conclusions on a dozen or so cases treated by a new method. For any therapeutic measure to be thoroughly tested the results must be based on a large number of cases which have been observed over a course of years.

Has experience, then, demonstrated the therapeutic value of the sanatorium treatment? From the mass of evidence that has now accumulated and from personal observation I am firmly of opinion that it has, provided that certain conditions have been fulfilled. In the absence of these the results have not been so good. The chief of these conditions are three in number: (1) if the disease was in the incipient stage and not acute when the patient first came

under treatment; (2) if the patient remained under active treatment for a sufficiently long period which, in most cases, I consider should be at least six months; and (3) if a healthy outdoor life could be subsequently followed. There may be a few exceptions to the last-named condition, but a return to an indoor and sedentary occupation is accompanied by serious risks of a relapse. I believe the sanatorium treatment of pulmonary tuberculosis to be the best that has hitherto been introduced, but at the same time it is by no means a specific, and only a certain proportion of the patients can hope for partial or complete recovery. Certain adjuvants may from time to time be introduced. In some sanatoriums Koch's old tuberculin is being used and satisfactory results are claimed. Further experience and lapse of time, however, are necessary before any definite pronouncement can be made as to this addition to ordinary sanatorium methods.

Another question asked is: "Are successful results obtained equally (a) in well-to-do patients and (b) in the working classes?" Up to the present I believe not, but I see no reasons why the results should not be equally favourable as I shall presently explain. Owing to circumstances more patients of the well-to-do classes are, under the present conditions of society in this country, able to abide by the three principles I have named above than is the case with those of the working classes. Further, the more independent the patient as regards the necessity of earning a living the better is likely to be the result.

I have to thank Dr. H. G. Felkin for supplying me with the statistics of 100 patients who have been under the care of himself and Dr. R. Mander Smyth at the Linford Sanatorium, Ringwood, New Forest. In the accompanying table the

¹ The Journal of the American Medical Association, Nov. 21st, 1903.

disease has passed beyond the stage when the chances of cure are highest. He dates his illness not from the commencement of the symptoms but from the time when he has to give up work. Even if the patient should come under medical observation when there is only slight infiltration in one lung and consents to undergo suitable treatment, if he or she be married, the thought of "home" and those dependent on their labour and care is constantly present and a natural source of worry and anxiety. Consequently, if improvement be manifested after a few weeks, the man is tormented with the idea that his wife and family are suffering from his absence from work and the loss of the income derived therefrom, and he insists upon returning to work when the reparative processes have only just begun, with the almost certain consequence—a relapse. The woman acts in a similar manner and against all advice returns home to her children and deplorable results ensue. Not only does she herself rapidly become worse, but there is possibility of her infecting others. These considerations naturally weigh less if the patient is unmarried and has no one dependent upon him or her. A longer stay in the sanatorium is then possible and a prospect of arrest of the disease more hopeful. But even if the first two conditions are fulfilled—an early diagnosis and six months' residence in the sanatorium can be carried out—all the benefits thereby attained may be ultimately set at naught by the patient returning to unhealthy surroundings and an unsuitable occupation. A man accustomed to outdoor life may be able to continue to pursue the course of life he has been taught whilst under active treatment. But what is a man who has been brought up as a clerk, a lithographer, a baker, or a tailor to do if he cannot return to his former means of earning a living? Such men know nothing of a country life and yet if they return to their former occupations relapse is most probable. Yet how, with the necessary change of work, can they hope to earn sufficient money to support themselves and those dependent upon them?

The majority of the patients who entered the sanatorium in the early stage of the disease and remained a sufficient length of time there will probably have been discharged as "greatly improved and fit for work." Other patients will have been sent out as "unfit for work" and advised to "take things as easily as possible." Inquiries into the future of these two classes yield peculiar results. According to statistics at the end of four years about an equal percentage are alive and able to do light work. The explanation is that those who were discharged "fit for work" returned to hard and unsuitable labour and surroundings and many of them speedily relapsed, whilst those "unfit for work" led quieter and more sheltered lives, capable, perhaps, of undertaking a little light work, and being carefully looked after by their friends or charitable institutions. They were thus able to drag on through an invalid life and did not suffer from severe recrudescence of active disease.

In the public mind "quiescence" is too frequently confounded with "cure" of the disease. Quiescence or temporary arrest may be brought about within six months under suitable treatment, but two or three years at least are required before "cure" can be pronounced. Here lies the difficulty in inducing patients to appreciate the consequences of "after-treatment" in the shape of suitable employment subsequently to leaving the sanatorium. Sanatoriums for the working classes, if they are to repay the money expended upon them, must be accompanied by farm colonies or other means to instruct the patients in suitable employment. Otherwise the ultimate results can only be disappointing.

This consideration leads to a third question. In the case of working classes, must an elaborate system of insurance

be combined with a system of sanatoriums and are convalescent homes necessary to prolong the treatment? To both these points I unhesitatingly answer "Yes." I consider that the proposed schemes for building such institutions will prove a failure unless insurance against disease is made compulsory. The idea that the institutions should be supported by the funds of trade unions, friendly societies, and kindred associations is excellent, but judging from the speeches made on the subject by those who are not medical men very wrong impressions have been created in their minds as regards the true significance of open-air treatment. The idea seems to have arisen that a person suffering from "consumption" has only to go to a sanatorium for a few weeks—"three months" is the term frequently used—in order to be "cured." Even in the case of highly educated individuals quiescence is mistaken for cure, and assemblies of working men receive with applause the announcement that the speaker has known fortunate individuals who have secured admission into a sanatorium for a few weeks to come out cured. Exaggerated notions are thus excited and the sanatorium treatment comes to be regarded as having an immediate and miraculous effect. Those who are intended to be responsible for the maintenance of these sanatoriums must be made to understand thoroughly the three principles I have already alluded to—early diagnosis, prolonged stay in the sanatorium, and subsequently suitable employment. In order to secure these essentials to the workers, I consider compulsory insurance to be absolutely necessary. A working man will far more willingly seek medical advice if he knows that if prolonged treatment is necessary his family will be supported during his absence. Consequently, instead of struggling on until he can work no longer, being afraid of losing a good situation, as soon as the early symptoms develop, such as cough and loss of weight, he would at once go to a medical practitioner in order to ascertain the nature of the malady. An early diagnosis would thus be much more frequent than in the present circumstances, and so the success of sanatorium treatment would be correspondingly increased. Further, the knowledge that his family would not be in want of the necessities of life would enable the patient to remain the necessary length of time in the sanatorium and so would diminish the risk of relapse. Aid should be forthcoming from the insurance funds to help to support the patient and his family until he could learn some outdoor employment. In such circumstances hopes of permanent cure would be considerably brighter than is possible under the present condition of affairs in this country. The oft-quoted German statistics, especially of the railway workers, demonstrate the advantages that can be gained by imposition of compulsory insurance.

If self-supporting sanatoriums are actually brought into existence one most important point must be insisted upon, and that is, that although the funds will be provided by trade unions and friendly societies, yet the management of details must be vested in the hands of medical men. As I have already several times pointed out, early diagnosis is all-important if success is to follow, and therefore the selection of cases must rest entirely with the medical officers and not with the officials of the supporting societies. For not only must the disease be in an early stage but indications of activity must be absent. The sanatorium will in a certain sense belong to the working men but that must not give them the right to nominate for themselves the patients who are to be admitted. If a worker is found to be suffering from pulmonary tuberculosis in an advanced stage there will naturally be a wish amongst his fellows, kindly disposed as they are, to "give that man a chance" by nominating him to a bed in the sanatorium and to try to insist on his admission. It may seem hard on the individual, and such a course may be deplored, but if the maximum benefit is to be

weeks "for the purpose of being educated" is not likely to lead to very good results. During a man's stay at a sanatorium there is a constant fight between the forces of the body, which are being strengthened, and the tubercle bacilli, which are being placed at a disadvantage. The principle of the survival of the fittest applies to micro-organisms and the last tubercle bacilli to succumb are probably the strongest. Consequently if a man leaves a sanatorium too soon it is possible that when he leaves there are a smaller number of bacilli in his lungs, but that these bacilli are more virulent as a whole than those present in his lungs when he entered the sanatorium. When such a man returns to the conditions under which he contracted the disease, he has to contend with the conditions which undermined his strength and possibly with a more virulent race of bacilli. In consequence it not infrequently happens that he dies sooner than if he had never gone to a sanatorium. Is it fair to attribute such a result to the defects of the sanatorium treatment?

Before expressing an opinion as to the value of sanatoriums it is necessary, in view of what I have just stated, to express a general opinion of what I mean by sanatorium treatment. The efficiency of a sanatorium depends entirely on the physician in charge of it. A sanatorium is one part hospital and three parts school. At such an institution, if properly conducted, a patient is taught to eat sufficient food and not to be afraid of fresh air. In other words, he is taught to return to a natural and healthy mode of life. The two factors, sufficient food and fresh air, constitute merely the elements of the great truth which anyone suffering from consumption has to learn if he wishes to remain permanently well when the disease has been arrested. This great truth is the necessity of avoiding everything known to undermine the strength of those forces of the body which deal with any invasion of micro-organisms. If a tuberculous individual in whom the disease has been arrested will not interfere with nature then nature, in the majority of instances, will overcome his disease. Fresh air and sufficient food are necessary if these bodily forces are to be in a position to overcome the invasion of tubercle bacilli but they are of comparatively little avail if the individual is allowed to become over-fatigued or is subjected to too severe a strain. What a patient learns at a sanatorium, and only at a sanatorium, is the fact that *fatigue* kills the majority of consumptives and causes the frequent relapses of the disease. The avoidance of fatigue is therefore of primary importance. This is recognised by all competent physicians but the principle has been carried too far by some. The Dettweiler school regard rest in bed or in liegehall for long periods as essential, and consequently many of the German sanatoriums are in reality convalescent homes to which a number of liegehallen are attached. Dr. Otto Walther of Nordrach and his school essay the more difficult task of following in Brehmer's steps and of proscribing gradually increasing exercise to their patients, as soon as their temperature shows that the disease is sufficiently inactive to permit it. This form of treatment is more difficult because the decision as to the amount of exercise to be taken demands great judgment. More than once I have been accused in the medical press—to my personal satisfaction—of holding a brief for Dr. Walther. I would repeat what I have said often before, that Dr. Walther's system of treatment is justified by its results and that patients who have had their bodily forces gradually and judiciously increased by means of exercise show, in my experience, more permanent benefit than those treated in liegehallen. This point requires emphasis because it is the key to the solution of the economic value of sanatorium treatment so far as the working classes are concerned.

Many a working man is discharged from a sanatorium with the disease quiescent and arrested but without having

had his capacity for manual work developed. On leaving the sanatorium he usually obtains employment of the kind which he has been accustomed to follow. He may still have fresh air and sufficient food and yet he relapses—why? Because his work tires him and undermines the natural forces of his body which deal with micro-organisms. He falls because he was not gradually educated back to work, according to his strength, before he left the sanatorium. Certain attempts to remedy this defect have been made but most of them have been half-hearted and not properly organised. In the German working men's sanatoriums the patients "play at being rich men" and so refuse to work whilst at the sanatoriums, as to do so would be contrary to their social democratic principles.

An organised attempt to send working men patients away from a sanatorium, not only with their disease arrested, but with an educated capacity for hard work, is being made at the Brompton Sanatorium at Frimley. This is due to the initiative of Dr. M. S. Paterson, who prescribes walking exercise for a period and then such manual labour as the condition of the patient may indicate. The patient is kept under strict supervision and gradually the amount of work is increased. The results so far have been impressive but no judgment can be passed on the success of Dr. Paterson's work until sufficient time has elapsed to show the permanency of the results. Personally, I did not think that the patients could have been educated so rapidly to full work without harm, but if the results hitherto obtained are maintained, the economic possibilities of sanatoriums for the working classes will be immensely increased.

What proof can be adduced of the therapeutic value of sanatoriums in the treatment of pulmonary tuberculosis? This question may be approached from several standpoints: (a) the opinion of physicians accustomed to deal with the disease; (b) the statistical results of sanatorium treatment; and (c) the more purely economic results.

Physicians who are accustomed to see large numbers of individuals suffering from consumption consider the sanatorium treatment superior to any other known method. This is sufficiently shown by the fact that after due trial of modified sanatorium treatment at both the Brompton and the Mount Vernon Hospitals for Consumption the physicians persuaded their respective committees of management to establish a sanatorium of 100 beds in connexion with each hospital.

The statistical results are not dealt with so easily. In the first place there are few available statistics of the results of treatment before the advent of sanatorium treatment which are drawn up in such a way as to show the economic value of the various forms of treatment adopted. Then, again, in England we have not at hand a sufficient number of trustworthy statistics of the results of sanatorium treatment. We are therefore obliged to draw on the results obtained in the sanatoriums erected for the German working classes. There are naturally fallacies in any comparison between results obtained in the treatment of consumption before and after the advent of the sanatorium treatment, but even when allowance is made for these I think that the subjoined tables clearly indicate that the results obtained to day show a decided improvement on the results obtained before 1870.

Dr. J. E. Pollock² published in 1885 the results of treatment in 3566 cases of phthisis in all stages which had been observed by himself. The average duration of life of all these cases from their first symptoms was 30.59 months. The results obtained to-day without sanatorium treatment are probably much the same as these. For example, Dr. F. C. Shrubbsall has kindly ascertained for me that the average

² Prognosis in Consumption, p. 77.

duration of life of patients who die in the Brompton Hospital is 25 months from the date of their first symptom. It is difficult to analyse Dr. Pollock's statistics for the purpose of comparing them with results obtained in German sanatoriums where a large proportion of the cases are in an early stage. It is best, therefore, to confine our attention to 194 cases observed by Dr. Pollock and labeled "chronic first stage," as these seem to have been the cases which gave the earliest manifestations. The following table shows the results obtained at the end of five years:—

Results of 194 Cases of "Chronic Phthisis in the First Stage" (1867).

	At end of			
	Second year.	Third year.	Fourth year.	Fifth year.
Dead	13 per cent.	42 per cent.	65 per cent.	83 per cent.
Alive but capacity for work not stated	37 ..	53 ..	54 ..	17 ..

Dr. O. J. B. Williams² stated that out of 7000 hospital cases of phthisis he could only reckon 24 instances of cure and 51 of partial cure with indefinite duration, or a total of 75; and out of 1000⁴ patients in the upper classes treated between 1840 and 1870 only 34 recovered completely, though 235 could be classed as well when regarded in relation to their general health. These results were in advance of anything previously published but no statement is made as to the time which had elapsed in the case of these 235 patients from the commencement of their disease—that is to say, of the length of time during which they had maintained their good condition, beyond the fact that they were "well" when last seen. At the best, then, 23.5 per cent. of Dr. Williams's cases amongst the upper classes were capable of "following their occupations without any recurrence of their former symptoms," whilst of Dr. Pollock's patients only 17 per cent. of early cases were alive at the end of five years.

In order to obtain the most recent and most authoritative information⁵ of the results of the German sanatoriums for the working classes, I recently paid a brief visit to Berlin where every facility was accorded me. The number of cases of pulmonary tuberculosis treated between 1897 and 1905 in the German sanatoriums for the working classes amounts to over 100,000, as may be seen in the following table:—

Number of Cases treated in German Sanatoriums for the Working Classes.⁶

	1894.	1893.	1892.	1891.	1900.	1899.	1898.	1897.
Men	16,957	14,957	12,187	10,812	8,442	6,032	3,805	2,593
Women	6,530	5,211	4,302	3,244	2,652	1,665	1,104	735

² Quoted in Dr. Wilson Fox's "Diseases of the Lungs and Pleura," in second edition, p. 333.

⁴ Pulmonary Consumption, by Dr. C. J. B. Williams and Dr. C. Theodore Williams, second edition, p. 327.

⁵ I take this opportunity of expressing my gratitude for the information placed at my disposal to Dr. Jur. Richard Freund, director of the Imperial Insurance Department in Berlin, Professor von Fannowicz, secretary of the Council of the International Association for the Prevention of Tuberculosis; Dr. Zacher, Imperial Privy Councillor, President of Senate in the Imperial Insurance Department; Herr Dieckhoff, Imperial Privy Councillor and President of Senate in the Imperial Insurance Department; and especially to Dr. A. Kerpeling.

⁶ Statistik der "Krankheiten" in Versicherungsstatistik und Invalidenversicherung für die Jahre 1900, 1901, 1902, 1903, 1904, 1905, pp. 6-7.

The results of the sanatorium treatment of these individuals to date may be tabulated thus:—

Results of each 100 Cases treated in the Sanatoriums.⁷

Discharged fit to work in 1900.	Remained capable of full work at end of—				
	1910.	1901.	1902.	1903.	1904.
Men, 72	65	48	40	35	30
Women, 72	67	52	46	40	33

Discharged fit to work in 1901.	Remained capable of full work at end of—			
	1901.	1902.	1903.	1904.
Men, 71	70	53	45	33
Women, 77	72	60	51	45

Discharged fit to work in 1902.	Remained capable of full work at end of—		
	1902.	1903.	1904.
Men, 77	72	57	45
Women, 80	76	62	54

The average duration of stay in the sanatoriums was 75 days and the average cost per patient was from £17 to £18.

Better results still have been obtained by the Prussian and Hessian State railway companies which have sent their employés to the German sanatoriums for the working classes.

Results obtained in Employés of Prussian and Hessian State Railways.

Year of treatment	1893	1899	1900	1901
Number of cases treated	217	354	429	532

Percentage of patients capable of full work in subsequent years	79% in 1899	83% in 1900	84% in 1901	84% in 1902
	63% in 1900	72% in 1901	72% in 1902	72% in 1903
	54% in 1901	61% in 1902	63% in 1903	63% in 1904
	45% in 1902	54% in 1903	57% in 1904	58% in 1905
	43% in 1903	49% in 1904	55% in 1905	

We see then that, viewed as a whole, every 100 cases treated in the German sanatoriums for the working classes provide at least 31 persons who are capable of work at the end of five years (not from their first symptom but after their discharge from the sanatorium) and that when the conditions are more favourable, as they are in the case of employés of the Prussian and Hessian State railways, out of each 100 cases treated, from 43 to 53 are capable of full work at the end of five years from the time they left the sanatorium. These results show that under present-day conditions treatment is more successful than it was before the advent of sanatorium treatment. At that time, as I have stated, 83 per cent. of Dr. Pollock's early cases were dead at the end of five years from their first symptoms, whilst the remaining 17 per cent. were probably more or less incapacitated.

A further argument in favour of sanatorium treatment is obtained from the duration of life of a German working man who does not go to a sanatorium, from the time that he begins to draw "incapacity pay." A German working man is entitled to draw pay from the insurance companies when he has been incapacitated by consumption for six months. It is found that of every 100 of such men between the ages of 25 and 29 years only 17 are alive at the end of one year from

⁷ Loc. cit., p. 41.

the time they commenced to draw pay and only four are alive at the end of four years.³

It is, of course, true that this advance in the value of treatment is in part due to the earlier detection of the disease by means of Koch's bacilli and other methods, but so far as statistics are of value they show that sanatorium treatment has done much to add to the economic value of consumptives.

The successful results of treatment in the German sanatoriums for the working classes depend very largely on the facts that year by year a more careful selection of cases is made and that a large proportion of patients admitted have the disease in its early phases. It is sometimes said that the German statistics are not reliable and that one great fallacy is the (asserted) fact that many of the cases stated to be cured have never suffered from tuberculosis. In answer to this I need only state that business men like the directors of the Prussian and Hessian State railways are so satisfied with the results obtained by sending their employés to the insurance sanatoriums that during the last year or two they have established two sanatoriums of their own. In these sanatoriums tuberculin is used to establish the diagnosis whenever there is any doubt and the results obtained to date are practically the same as those which I have given above.

So far from thinking that it is impossible for us to approach the German results in England, I am convinced that these results would be much enhanced and that the permanency of the results obtained would be increased if the methods of treatment adopted in the German sanatoriums were changed. Many of these sanatoriums, as I have already said, are simply convalescent homes with liegehallen attached. The majority of patients are kept in the liegehallen for five or six hours a day but when they are within the buildings of the sanatorium they do not have a very free supply of fresh air. The buildings, it is true, are perfect but all the rooms are supplied with double windows and during the greater part of the winter the double windows are kept shut and only the fanlights are slightly open. To show the views of the physicians in these sanatoriums I would mention that some of them in the winter shut their bedroom windows at night and admit air into their bedrooms through a door leading into a sitting room, the window of which is kept partially open. The reason given to me for this procedure is that the climate in the neighbourhood of Berlin is so bad. It is interesting in this connexion to remember that many writers in England have said that it is impossible for us to obtain the same results as are obtained in Germany because the climate in Germany has so many advantages over our own.

The German sanatoriums for workers have so far failed in another respect. The arrangements for educating patients, whilst they are undergoing treatment, to a capacity for work have not succeeded, partly because of the liegehalle system and partly because the German working man refuses to do work which may possibly be remunerative to the institution. So far as I can obtain the facts, it would further appear that up to the present time the so-called agricultural colonies in connexion with these sanatoriums have also proved a failure. Some of us, I think, may expect too much from agricultural colonies on a large scale. Patients when they leave a sanatorium are often advised to spend the rest of their lives under open-air conditions and to avoid office work and the like. We must not forget the important part played in relapse by strain or that in open-air occupations, such as in the manual labour of farm work, there is much more strain and therefore more fear of relapse than in office work. Many patients

cannot stand the fatigue involved in manual labour to which they have hitherto been unaccustomed and such patients, in the experience of men of much authority on the subject, do better and are more likely to remain permanently well if they return to office work, to which they are accustomed, under reasonable conditions of hygiene, than if they engage in pursuits which entail much muscular strain. Then, again, it has been found in Germany that many workmen previously trained to other businesses can never be trained to become remunerative employés in agricultural colonies.

When I am asked whether equally good or better results can be obtained in the well-to-do classes I would say that the answer depends almost entirely on the character and backbone of the individuals concerned. The treatment of consumption is mainly a question of commonsense and of pounds, shillings, and pence. A man of some means who has the disease detected in its early phases has better opportunities of being admitted at once to an efficient sanatorium than members of the working classes, and on leaving the sanatorium he has better opportunities of leading a suitable life under good conditions. Working men do not enjoy such good opportunities as the well-to-do but they are perhaps more likely to follow medical instructions to the letter, and consequently when their conditions are favourable they are a greater credit to the sanatorium method of treatment.

If we turn to the blunt question, Do the German insurance companies make or save money by the establishment and maintenance of sanatoriums? there is some difficulty in obtaining an answer which gives a true perspective of the financial results. The reason for this is that in Germany the whole question is approached from the statesman's point of view, with the ultimate object of eradicating tuberculosis. In England we approach the question from the philanthropist's point of view, with the immediate object of relieving the suffering of a certain proportion of the present generation. The German authorities recognise that they cannot restore many of those who are suffering from advanced tuberculosis, to a condition of lasting economic value, and they accordingly concentrate their energies on detecting the disease in its early stages, on arresting the disease whilst it is possible to restore the individual's capacity for work, and on preventing the spread of infection from those cases which are beyond permanent benefit. Such a system costs money and so far expenditure outbalances the ascertainable savings, but there can be no question that in 20 years the German nation will be able to prove conclusively the financial return of their present policy. Already there is an indication of the value of their methods. As is well known, every German workman with an income of less than 2000 marks a year is forced by law to insure against sickness. The workman pays two-thirds and his employer one-third of the necessary contribution. Any workman so insured is entitled to a certain rate of pay for a certain period of time if he is incapacitated from work by tuberculosis or other disease. For the first few years after the law was passed compelling insurance the amount of money paid out by the companies to those incapacitated by tuberculosis steadily increased. Sanatoriums for the insured have been established for eight years and during the last few years the amount of money paid out for incapacity for work due to tuberculosis of the lungs has begun to diminish so far as the companies connected with Berlin and its neighbourhood are concerned. The number of men per 1000 receiving money for incapacity to work through consumption has fallen progressively in the last three years from 281 to 216, and in women from 163 to 119 per 1000.*

Such results are most suggestive of eventual monetary

* L'Etat de la Lutte contre la Tuberculose en Allemagne. Memoir presented to the Paris Tuberculosis Congress, 1905, by the Central Committee for the Erection of Sanatoriums for Consumptives in Germany, pp. 34, 35.

* Verwaltungsbericht der Landes-Versicherungsanstalt Berlin für da Rechnungsjahr 15

The following summary of registered provident societies and certified and Post Office savings banks in Great Britain and Ireland on Dec. 31st, 1903, may be of interest as showing the wealth of the industrial classes, exclusive of their contributions to many insurance companies, such as the Prudential Company. It is taken from the Report of the Chief Registrar of Friendly Societies, 1904. It must be remembered that there are many claims on this capital, and that it belongs to the thrifty working man and not to the poor or to the "unemployable."

Note.—Where returns are made to a date other than Dec. 31st the particulars at the nearest date available are given.

The Poor-law institutions spend, yearly, large sums on consumption (for example, one-third of the deaths from consumption in London take place in Poor-law infirmaries). Again large sums of money are spent on consumption by convalescent homes, consumption and other hospitals and dispensaries, and by many charitable bodies, such as the Charity Organisation Society, ladies' visiting societies, and institutions for the dying. In my experience, too, employers are often willing to give financial and

other assistance to their workmen for the purpose of sanatorium treatment if such workmen have proved loyal and useful. There are, in addition, said to be some 600 sanatorium beds available in England. We might have, but at present do not have, assistance from such bodies as the Metropolitan Asylums Board.

In a condensed article of this kind it is impossible to deal adequately with the part that might be played in a general organised scheme by all these bodies and agencies to which I have alluded, but I think that hospitals, especially hospitals for consumption, might model their procedure on the line of what is done in Berlin so far as the detection of the disease in its early stages is concerned. I would say a word or two on the possibilities of the workmen's societies. In Germany the workmen forced the Government to deal with the question, for the insurance system was elaborated in direct reply to the criticisms of the Social Democratic party. In England the industrial classes are awakening to the necessity of action and they have realised that if action is to be taken the workmen must help themselves. Therefore I regard the National Association for the Establishment of Sanatoria for Workmen Suffering from Consumption, which is presided over by H.R.H. Princess Christian, as having initiated one of the most important movements of our time. I believe that this association, which owes its origin largely to Mr. W. G. Bunn, secretary of the Hospital Saturday Fund, has the remedy in its own hands if it can but attract the moderate support of philanthropists and if it associates itself in some organised way with other existing institutions and societies.

To take one example. Mr. Burnes, the secretary of the Hearts of Oak Benefit Society, has made an examination into the sickness experience for the past ten years of those members who died in 1904. Mr. Burnes found that each member who died from consumption before 40 years of age cost the society £17 17s. more than a member who died from some other disease before 40 years of age. In 1904 deaths from all causes were 2110; of these 377 died from consumption at average age, 40 years. Of the total (2110) 673 died under 40 years of age, of whom 33 per cent. died from consumption. On the basis of the German statistics it is probable that those who were restored to work by sanatorium treatment would in time provide, by means of their quarterly payments, not only enough money to balance the expenditure on themselves but a proportion of the expenditure on those whose capacity for work was not restored.

Let us take another example—that of the Post Office employés. In the years 1896-99 the loss per 1000 living in the general population of Great Britain and Ireland¹² was 1·3, whilst the loss per 1000 living in the Postal Service was 1·97, and yet Mr. Garland has shown that sufficient funds, for the efficient treatment (in sanatoriums) of postal employés who contract consumption, can be obtained if the employés will submit to a deduction of pay to the extent of less than $\frac{1}{2}$ d. a week, or of some 2s. a year. Over 30,000 employés have consented to such a deduction and the late Postmaster-General (Lord Stanley) arranged that the deduction should be made at headquarters and that anyone sent to a sanatorium should be entitled to six months' leave on full pay. There should be little difficulty in persuading the directors and employés of large industrial concerns, such as the railways companies, to follow the excellent example set them by the Post Office organisation.

These two instances are sufficient to show that the financial difficulties in England are not so formidable as might be thought. I think that the time has arrived for a Government inquiry into all the aspects of the subject. The question can be solved if there is coöperation between existing institutions and societies and if the working

¹² The Post Office and the Prevention of Tuberculosis, Mr. Charles Garland, THE LANCET, Sept. 14th, 1901, p. 723.

population will contribute a small weekly sum for the purpose.

I would therefore express my opinion, in answer to the request of the Editor of THE LANCET, that sanatoriums are essential to the treatment of tuberculosis and that, if properly used as an important part of a co-ordinated system, they are invaluable to a campaign directed towards the eradication of tuberculosis. If I am asked how a county authority or a private philanthropist can best spend money on those afflicted with consumption, I would answer that money would be best spent on co-ordinating our present forces and that no money should be spent on the erection of sanatoriums unless these institutions are to form part of a complete scheme such as I have briefly sketched.

What we lack at the present time is any scheme of co-operation between philanthropists and the societies of the working classes. We have no organised plan to deal comprehensively with the whole question with the ultimate object of eradicating the disease. If we are to have success we cannot continue without some central authority for tuberculosis. Our system to be of service must be perfected; cases must be detected in their early stages and dealt with; money or work must be provided for families when the breadwinner is away, and steps must be taken to prevent the spread of infection from advanced cases.

Brooklyn, N.Y.

SANATORIUMS FOR CONSUMPTIVES.

By F. R. WALTERS, M.D. LOND., M.R.C.P. LOND.,

PHYSICIAN TO THE CROOKSBURY SANATORIUM, LATE PHYSICIAN TO THE MOUNT VERNON HOSPITAL FOR DISEASES OF THE CHEST.

OWING to the absence of a descriptive name for the treatment adopted in open air sanatoriums some confusion is often noticeable in discussions on the subject. Few medical men will be found to advocate a return to the warm room and shut-window methods of a generation ago, few will venture to dispute the value of any essential detail of sanatorium treatment. There is general agreement, in theory at least, as to how a consumptive should be treated; but there is not yet the same unanimity as to where the treatment should be carried out, whether in an institution or in the patient's own home. Those who are best acquainted with sanatorium methods are the first to recognise the difficulties of open air treatment at home. The average home, whether middle class or artisan, is by no means ideal for the purpose, and it is usually expensive and sometimes impossible to make it suitable, to provide proper cross-ventilation and approximate freedom from dust and atmospheric impurities indoors, and convenient shelters and walks out of doors. Sanatorium treatment involves a reversal of ingrained habits usually shared by other members of the household, so that a change of surroundings for a time is distinctly advantageous, just as with a Weir Mitchell case or a habitual inebriate. Hygienic treatment depends for its efficiency on the personal attention of the medical adviser. Supervision in the home is necessarily imperfect and for a number of patients well nigh impossible. Take, for instance, the early visit of the day, when directions are given for the morning. Assuming that there are 50 patients to be seen in as many houses, and that these are five minutes' walk from one another, it will take well over four hours to give the patients the briefest possible personal directions, whereas these should be given at latest by breakfast time. In a good sanatorium it is usual for the medical officer to see each patient several times daily, to watch the effect of his walks on pulse, respiration, and temperature, to take the chief meals with him, and generally to keep in touch with him throughout the day, and although some of these duties might be delegated to a competent and specially instructed

nurse, it would still be physically impossible for one medical officer to supervise a number of patients in their own homes.

Just as with hospitals for the poor, so with sanatoriums, there is an advantage in treating many patients together, as laboratories and apparatus required for one patient are equally available for a number, and greater uniformity as well as greater precision of treatment can be insured at less expense. This advantage is likely to increase rather than to diminish with the more general adoption of special tests and methods of treatment, such as the opsonic test and the treatment by tuberculin or by specially prepared sera.

When we turn for confirmation of these advantages to the results of treatment we are met with many statistical difficulties. There are no complete statistics of treatment in patients' homes, and in this country only recent ones of sanatorium treatment. The average duration of treatment, the proportion of early and advanced cases, the completeness of hygienic supervision, and other details are most variable, so that a comparison under similar conditions is not yet possible. In the official report for 1905 of the German Central Committee for the Frection of Sanatoria for Consumptives, the results of seven years are given, including in all 3420 cases which had been fully investigated. It appears that from 79 to 86 per cent of those treated were still fully fit for work at the end of the first year, from 63 to 76 per cent at the end of the second year, from 54 to 67 per cent at the end of the third year, from 45 to 58 per cent at the end of the fourth year, from 44 to 54 per cent at the end of the fifth year, from 40 to 45 per cent at the end of the sixth year, and 37 per cent at the end of the seventh year.¹ These are the results of a course of treatment of less than three months on an average, which is insufficient to cure even an early case as a rule, after which the patients have mostly returned to the same conditions of life as those in which they were attacked. Taking these facts into account, the results are as good as can be expected, and much better in all probability than those of treatment at home. For really successful results early and prolonged treatment is needful, as well as suitable after conditions; whereas it is notorious that in this country most patients, whether middle class or artisan, usually present themselves when the disease is already extensive and the general health undermined, stay much too short a time, and then return to more or less unsatisfactory conditions of life. No wonder if there are many incomplete recoveries and many relapses. But how would this be remedied by substituting inferior hygienic conditions and increasing the difficulties of medical supervision? The proper remedy is to attack the causes of failure to increase facilities for early diagnosis and treatment to prolong the fresh air stage, and to provide better after-care.

Judging by personal impressions and comparing ten years of out-patient work at a chest hospital with two or three years as physician to in-patients, there appears to me an overwhelming superiority in the latter department. Indeed, I have been sometimes tempted to regard out-patient treatment of consumptives as sheer waste of time. Turning to a different class, I have a fairly large and increasing list of gentlefolk who have undergone sanatorium treatment during the last five years and remain well and at work, whereas I scarcely remember a single instance of recovery in this country under treatment at home. I have met with several cases in which open-air treatment was attempted at home or in apartments previously to admission to the sanatorium, and have been struck with the difference in results. Such patients freely confess after a few weeks' sanatorium treatment that they had unintentionally wasted their time at home, that home treatment was quite a different

¹ In each case the higher figures represent the latter results, which have been better year by year.

thing owing to the difficulties imposed by their surroundings, and that less progress was made in months at home than in weeks at the sanatorium. I have also had most flattering letters from medical men testifying to the educational value of sanatorium treatment; and this is not the least of the advantages conferred. I think, however, that these educational advantages should be extended to other members of the patient's household, and instead of excluding visitors absolutely, as is done at some sanatoriums, they should be encouraged to stay now and then at the sanatorium. This proceeding undoubtedly somewhat increases the difficulties of the medical director, but is likely to greatly reduce the opposition which the patient has to contend with on returning home.

Admitting, then, that institutional treatment is more satisfactory than home treatment during the active stage of the disease, what kind of institution should be adopted? Our chest hospitals and infirmaries have played a large part in reducing the mortality from consumption, but they are insufficient to give an adequate course of treatment to every patient who is suitable for admission, and they labour under the drawback of being mostly urban and provided with too little ground to permit of progressive walking exercise. If, then, we have to increase the accommodation it would best be done by opening sanatoriums in suitable country districts for pulmonary cases and others at the seaside for surgical tuberculosis. Some of our present convalescent homes are doubtless suitable for the purpose; but their beds are already overtaxed by a different class of applicants, and they would have to be reorganised to make them suitable for pulmonary convalescents. Such convalescents are still liable to feverish attacks and relapses in which they would require nursing. They have to be warned against occupations and amusements which are harmless to non-pulmonary cases, they require more daily medical supervision, and if they still have a cough with expectoration suitable rules have to be enforced. The mixture of pulmonary and non-pulmonary convalescents would be a mistake and each home should receive exclusively one or other kind. It is also better as a rule to separate the more serious cases from the slighter ones, as the former are depressing to the more convalescent and require more absolute rest and quiet and more constant nursing. In a large institution the separation could be effected by means of a separate block or building or group of chalets, but wherever possible the seriously ill should go to a different institution. The admixture of consumptives from different social classes is also not likely to work well in England. It is extremely doubtful whether as great a mixture as occurs in the Swiss cantonal sanatoriums would be tolerated in England. In the same way pauper cases would have to be separated as a rule from non-pauper working-class cases.

In the erection of sanatoriums for the poor it is not advisable to build massive structures of many storeys. Simple inexpensive buildings of one or two storeys, like the one at Holt, in Norfolk, or like some of our chalet sanatoriums, are more suitable and also better, because more like the cottages in which the patient should live when recovery is complete.

What objections are there to the erection of a sanatorium in any particular district? These are mostly sentimental and founded on ignorance. The erection of large sanatoriums in small villages abroad has led to a diminution in the mortality from consumption amongst the villagers, and there is absolutely no evidence that a properly managed sanatorium is a danger to the neighbourhood. People who talk of a sanatorium as being tenanted by a miserable herd of invalids are obviously innocent of any personal knowledge of the subject, as the patients at a sanatorium are proverbially cheerful and healthy looking. Any sanatorium which is an exception to this rule should raise grave doubts as to its

proper management. It is, of course, a trial to be banished from home for months, but if visitors were more freely admitted this would be much less felt.

There is, however, another side to the prolonged course of treatment. It is justly argued that prolonged idleness is apt to foster lazy habits and to make the patient less capable of steady work. The remedy for this is to substitute other forms of useful occupation as soon as the patients are fit for it. Hard manual labour is unsuitable for something like two years after the breakdown, but many forms of light work are permissible as a rule, such as hoeing, raking, sweeping, pruning, poultry feeding, chopping up thin pieces of food, and some of the work in which hand machinery is used. The spare time should, however, be chiefly employed in education. At Dr. Weicker's sanatorium for artisans in Silesia and in some others the patients have regular courses of instruction in shorthand, foreign languages, cooking, and the like. Many of the applications of science and art to manufacture would also be permissible, such as designing, photography, the reproduction of designs, some methods of decorating pottery, and some of the applications of microscopy and chemistry. A conference of medical men with technical instructors in various branches of handicraft would probably bring to light many useful occupations open to convalescent consumptives. The chief point to bear in mind would be the substitution of delicate for laborious work, brains for brawn. That hygienic teaching bearing upon the disease itself would be given is taken for granted; but the addition of suitable technical teaching would make the sanatorium a valuable educational centre, would add to the happiness and usefulness of the inmates, and greatly diminish the difficulty in finding work for discharged patients.

The remaining objections to sanatoriums are really at bottom financial. Such institutions are of necessity expensive to erect and to maintain; there is also the maintenance of the family to be provided for and the support of both patient and family until remunerative work is obtained. It should be quite possible to erect a simple but satisfactory working-class sanatorium for £100 per bed, perhaps even less. Now that our wealthy classes are beginning to interest themselves in such matters there will probably be less difficulty in starting fresh sanatoriums if only the nation is convinced of their usefulness. The cost of maintenance will vary from 2s. to 5s. per head per day, according to size and management. Further expenses will be incurred for technical instruction, but this is really in the long run remunerative expenditure. It would be a mistake to cut down the staff, as this inevitably causes inefficiency. Even though some of the lighter duties are undertaken by the convalescent patients, as in so many of the German sanatoriums, the consumptive will never repay the cost of his keep by what he does while under treatment. The chief object in giving him duties to perform will be educational, not pecuniary. These expenses will have to be met for about six months on an average in early cases, from eight to 12 months in more advanced cases, unless there is a model village in connexion with the sanatorium to which patients can be drafted. At the Adirondack Cottage Sanatorium in America each patient is usually expected to spend the greater part of a twelve-month under treatment; and the durability of the results is likely to be within limits proportional to the duration of treatment.

A supplementary society will be needed to look after the family; and if it were possible to transplant the latter to a model village a great step would be gained, as the patient could then join his family in suitable quarters when convalescent. Although celibacy is useful and in some stages indispensable, this could not indefinitely be enforced in the case of married patients, and the advantages of better

quarters and medical supervision of the family would outweigh the disadvantages of a non-celibate life. Submission to medical rules would be made a condition of admission to the model village. Gross breach of rules would entail dismissal. Many occupations unsuitable in towns would be quite harmless if transplanted to the model village. Possibly the co-operation of some of our large manufacturers could be secured for such a scheme. There would be less difficulty in starting purely rural occupations, such as the production of fruit and vegetables and poultry keeping. This is done in connexion with the Montefiore Home in New York, whose country branch supplies most of the fruit, vegetables, milk, and butter required by the urban hospital. A similar arrangement is contemplated at the Gateforth Hall Sanatorium, near Leeds. Much the same object is kept in view in the agricultural colonies which receive the convalescent lads from the Villiers-sur-Marne Hospital in France.

Apart from the model village, which is the logical outcome of sanatorium treatment, but which would take time and careful organisation to establish, it may fairly be argued that the actual cost of treatment in the sanatorium would be no heavier than the prolonged treatment in an infirmary which usually precedes death from consumption in our working classes. Dr. A. Newsholme has shown that the average duration of such treatment has lately been 221 days in the Brighton Infirmary. He makes out a strong case to prove that such segregation in the most infectious stage of the disease is an important cause for the immense reduction in the mortality from pulmonary tuberculosis in England and that where dispensary or home treatment is substituted there has been no such reduction. But if prevention is better than cure and the patient can be restored to working capacity for several years, and in many cases permanently, by sanatorium treatment, surely this will be at least as good an investment for the nation's money. Even supposing that on an average one half break down after five years and become a burden on the rates, we may fairly set against this the fact that if treated at home they would have infected fresh cases, and that for five years they have been maintaining themselves and their families. There is already reason to believe that the results of treatment are gradually improving, and with the more general use of special methods of treatment a much larger proportion of permanent recoveries will probably be obtained in future.

How the expenses of sanatorium treatment will best be met, whether by voluntary effort or by national or local subventions or all combined, must be decided by public opinion in the light of actual experience. Doubtless a large scheme of insurance against sickness, as in Germany, would be of the utmost value; but much has already been done in England by local effort and a number of county sanatoriums are already in working order, supported partly by voluntary subscriptions, partly by grants from various local authorities, and partly by payments from those under treatment. The Durham County Sanatorium, which was one of the first to be established, owes its existence to co-operation between local medical men and others with the working classes, for whom it is designed. Its funds are derived partly from payments of 3d. per quarter from the latter, partly from weekly payments by inmates who do not subscribe regularly, supplemented by subscriptions from the wealthier classes, and by subventions from district councils, boards of guardians, &c., at the rate of £75 per bed per annum. Regular subscribers have precedence for themselves and their families to the extent of their subscriptions. The latest outcome of this method is to be found in the Workers' Sanatorium about to be established in Kent.

Another class of sanatoriums is represented by the Liverpool parochial sanatorium at Heswall, which receives exclusively patients who have resided for a time in one of the Liverpool workhouses. This institution has been somewhat severely criticised owing to the small proportion of recoveries

obtained; but such criticism is, in my opinion, unreasonable. The proportion of advanced and incurable cases is necessarily large; the patients are derived from those whose physique is very poor even apart from their disease; and if a convalescent leaves the building he almost necessarily returns to the least suitable kind of home. Such institutions have a claim to support for the lives they save, not so much amongst the patients as amongst the general population. They receive the patients from the poorest kind of homes which would quickly become centres for the spread of consumption. Even if none of their inmates ever recovered they would be worthy of support.

In conclusion, I would plead for a comprehensive scheme of treatment. If the thing is worth doing at all it is worth doing thoroughly and from the moment a consumptive is received in a chest hospital or sanatorium he should be provided for or assisted according to his needs, until he obtains remunerative employment under fit conditions or until he dies. When his disease is quiescent he should be drafted from the chest hospital to the country sanatorium and thence to the model village if his original home is distinctly unsuitable. If, on the other hand, the progress is unsatisfactory, he should be either kept in a special portion of the chest hospital or transferred to a special home in the suburbs or in some accessible country place. Transfers could take place between this home and the sanatorium according to need, so as to diminish the staff necessary for the latter and bring the patient nearer to his friends. Combined with these institutions should be societies for giving help to patients' families and advising them in matters of hygiene and to find work under suitable conditions for discharged patients; also to supply instructors in technical and other subjects of the right kind for those under treatment. All sanatoriums should be subject to inspection by a central body such as the one administering the King's Hospital Fund, which would make grants to the deserving institutions as in the case of the hospitals. There is no reason why every branch of such a comprehensive scheme should not be started simultaneously, even if only on a small scale to begin with, for each could help the other. The sanatorium, as Knopf has pointed out, is of incalculable benefit to the whole community for the social lessons it inculcates in hygiene and orderly living, in sobriety, cleanliness, and self-restraint. "It cures the consumptive whenever his case is curable and demonstrates the curability of the disease independently of climate. It makes the patient a hygienic factor when he returns to his former environment and demonstrates the preventability of tuberculous diseases. It not only diminishes tuberculosis amongst the masses but makes their lot a happier one, furthering charity, humanity, and liberty."² And if the happy day should ever dawn when tuberculosis is extinguished the sanatoriums will be available as homes for the aged and infirm who crowd our almshouses and poorhouses and as convalescent homes for the overworked and underfed of our cities and towns.

Farnham, Surrey.

² S. A. Knopf, *New York Medical Journal*, Oct. 21st, 1905.

BRISTOL ROYAL HOSPITAL FOR CHILDREN.—At the annual meeting of the "ladies' auxiliary" in connexion with this institution it was reported that £479 had been collected for the hospital, whilst the "ladies' guild" had contributed a large quantity of bed-linen and garments for the patients.

HOSPITAL SATURDAY FUND AT EXETER.—The committee of this fund has distributed the £350 which were the result of this year's collections as follows: Royal Devon and Exeter Hospital, £165; West of England Eye Infirmary, £72; and Exeter Dispensary, £21; the remaining sum being allocated to the smaller medical charities and convalescent home. During the past 24 years £15,950 have been raised by this fund, of which £14,500 have been given to the different medical institutions.

A MEDLEY OF SURGERY.

By PROFESSOR E. E. GOLDMANN.

[Professor Goldmann, Extra Professor of Surgery in the University of Freiburg, in Baden, being recently on a visit to London, delivered at a meeting of medical men in the house of a friend a clinical address dealing with various interesting surgical points arising out of original and most ingenious observation. The lecture, which was fully illustrated by lantern slides, was listened to with great interest by those present and there was general regret expressed that Professor Goldmann had not made arrangements by which his remarks could have been heard at one of the learned societies. Professor Goldmann, through Mr C. A. Ballance, has kindly placed his manuscript and illustrations at our disposal.—ED. L.]

as a valuable accessory in diagnosis to surgeons as well as rhinologists. An exact image of the frontal sinus is obtained by the x rays: the patient, lying on his stomach, is so placed on the photographic plate that the x rays pass through the skull in its antero-posterior diameter. By means of the cylindrical diaphragm designed by Albers Schonberg of Hamburg the best results are obtained. According to the age of the patient and according to the thickness of the skull a soft or semi soft tube is used, the time of exposure varying from one and a half to two and a half minutes. The following plates illustrate how accurately the x rays enable us to determine the exact form, size, and extent of the frontal sinus in its bitemporal diameter. We can easily recognise its frontal, temporal, and orbital recesses and can even discern those frontal cells situated below the frontal process of the upper jaw bone which are so frequently affected in disease of the frontal sinus. By a slight modification in the position of the patient the antrum Highmorei and the naso lacrymal duct appear on the plate. The x rays not only prove the existence of a frontal sinus but also show its symmetrical or asymmetrical development,

FIG 1.

Healthy frontal sinus with probe in right half

FIG 2.

Suppuration in left frontal sinus characterised by deep shadow, right half healthy

FRONTAL SINUS.

Killian's operation for the radical cure of frontal sinusitis has created a demand for a more accurate method of determining the anatomical and pathological conditions of the frontal sinus. Intranasal examination by probe or by means of illumination may reveal important points as to the particular form of disease in the sinus yet fail to illustrate certain facts essential to the operator. The following method which I have applied in numerous cases during the last two years has proved most serviceable and has been welcomed

its complete or incomplete division by a median septum or abnormal osseous lamina. In short, it supplies the surgeon with a mass of detail of importance to him before he enters upon the operation. By passing a probe into the frontal sinus and then exposing the skull in its bitemporal diameter good results bearing upon the depth of the frontal sinus may also be obtained. I have no hesitation in declaring that this method may likewise be of great help in diagnosing pathological conditions of the frontal sinus. In several cases suppurative conditions of the frontal sinus associated

with thickening of the mucous membrane and the periosteum were diagnosed, a deep opaque shadow marking the disease half of the sinus. The operation subsequently corroborated our diagnosis. Although the x rays cannot take the place of the older and more complicated methods of intranasal examination yet improvements in their application and greater experience in reading the plates will undoubtedly tend to enhance the value of the new method (Figs. 1 and 2).

RADIOGRAPHY OF THE TRACHEA AND INTRATHORACIC GROWTHS.

Surgical operations on the neck and its viscera have multiplied considerably within the last two years. Most pathological conditions connected with intumescence of the diseased organ produce changes in the trachea affecting either its anatomical position or its interior. The laryngoscope fails in many instances to give full account of such changes as may at any time necessitate immediate surgical relief. Great progress towards more exact diagnosis of these changes was achieved by tracheoscopy, but tracheoscopy can only flourish in the hands of the experienced specialist. Even Killian and Wild have been obliged to confess that in children and old men their method has often proved impracticable. Bruns and his pupil Pfeiffer have recently published a method which is being used by all surgeons like myself working in districts where tumours of the neck, above all goitrous tumours, are frequent and give rise to great difficulties in diagnosis. The new method, which consists in taking an x ray photograph of the trachea, is applicable in all cases, causes the patient no discomfort, and supplies the surgeon with a bank of diagnostic evidence which he requires. What we photograph is not the trachea itself but the air which it contains. The x rays being absorbed in a varied measure by the walls of the trachea, its surroundings, and above all things by the cervical vertebrae, the radiographed trachea stands out in marked contrast and in many cases is discernible as far as the bifurcation. The photographic plate is placed under the patient's throat; the diaphragm, of medium width, is so focussed that the converging x rays meet in the median line

FIG. 3.

Stricture of trachea due to compression by goitre from both sides. Dilatation, opposite α , above strictured section.

at a point corresponding to the sixth and seventh cervical or the second dorsal vertebrae in cases of intrathoracic growth. Soft tubes are used; the time of exposure is from two to three and a half minutes in adults and from one and a half to two minutes in children. This method shows the exact

position of the trachea, the changes in its form and position produced by the tumours pressing upon it, and the form and locality of the tracheal stricture. In all my cases the result obtained by the x rays has been corroborated both by operation and previous tracheoscopy. It should be remarked that the photograph determines the trachea in its entire length, whereas by tracheoscopy only sections of the trachea are seen, great experience therefore being needed to form an adequate conception of the trachea as a whole. As very delicate contrasts of shadow may prove of supreme diagnostic value it is essential to examine the negative and not to rely upon proofs. The following plates (Figs. 3 and 4) may

FIG. 4.

Radiograph of trachea and intrathoracic growth; trachea (white line starting at α) pushed to the left by goitre.

demonstrate how valuable this new method of examination is for determining the relations existent between intrathoracic growth and the trachea.

OPERATION FOR CARDIO-SPASM (ACUTE DILATATION OF THE OESOPHAGUS).

Cardio-spasm is a name recently applied by Mikulicz to a form of disease known to pathologists for many years as idiopathic dilatation of the oesophagus. It was styled "idiopathic" because no immediate mechanical or pathological cause for its formation could be found—even after careful post-mortem examination. Oddly enough, where cancer is associated with cardio-spasm the growth is found above the dilated portion of the oesophagus. The seat of the trouble is usually confined to the lower two-thirds of the gullet. It varies in dimensions. In advanced cases the sac may hold one litre of fluid. The diaphragm divides the dilated portion of the oesophagus into a thoracic and an abdominal section. As a rule, the mucous membrane of the oesophagus is in a condition of chronic inflammation and at times shows multiple ulcers on its surface. In accordance with the size of the sac the condition of the muscular coat varies, showing hypertrophy in one case and atrophy in another. Since the disease has become the subject of more careful clinical study and since our methods of its diagnosis have been more perfectly developed great attention has been paid to its etiology. A review of the literature on the subject tends to prove that various causes may produce it. It seems beyond doubt that oesophagitis combined with a primary disturbance in the mechanism of the cardiac functions is at the root of the trouble. Physiological

for their distribution and spread. The portal capillaries in the liver, the glomeruli in the kidneys, for instance, may serve as a barrier which excludes tumour cells from the general circulation. As Weigert has put it: "In malignant growths one system of capillaries shields the other, serving

FIG. 9.

Sarcoma cells invading wall of a small bronchus.

as a kind of filter to the rest of the body." Any channel passing through the area of cancer may become the means of spreading the growth. I have given special attention to the finer ramifications of the bronchi, mammary ducts, bile-ducts, and hair follicles. (Fig. 9.) In all these

FIG. 10.

Cancer cells invading a mammary duct.

organs lymphatics pass through their various muscular and fibro-elastic coats and end immediately below the epithelial lining. These lymphatics are the media through which the tumour cells pass in invading the duct walls. We

therefore find the cancerous deposits penetrating up to the epithelial lining. The membrana propria and the epithelial lining form a line of defence for the aperture of the duct for a long time. In many cases the cancer cells never enter the duct, but when they do nothing stops their growth and spread along the whole length of the duct system. (Fig. 10.) In connexion with such cases I must mention two most interesting and important facts. The epithelial lining of the ducts may remain unchanged under the cancerous thrombus, thus proving that the so-called cancerous infection of epithelial cells does not exist. Then, again, when the duct is blocked by the cancerous growth the tumour cells very soon degenerate. The cause of this degeneration is the absence of blood-vessels, since an organisation of the duct thrombus, such as occurs in the cancerous thrombus of blood-vessels, does not take place. Necrosis of cancerous thrombi in blood-vessels and lymphatics is the exception and in ducts the rule.

I must confine myself to these bare outlines of my histological research. I must refrain from entering into a discussion of the important question why sarcoma and carcinoma, although histologically so alike in their relation to blood-vessels, yet differ so markedly in their mode of generalisation. These and many other questions in connexion with the biology of malignant growths are engaging my attention at present and I hope that on some future occasion I may have the honour of communicating and demonstrating the results of my work in this respect to you again.

(To be concluded.)

A CASE OF OCHRONOSIS.

By FRANK M. POPE, M.D. CANTAB., F.R.C.P. LOND.,
PHYSICIAN TO THE LEICESTER INFIRMARY.

With a Note on the Relationship of Alkaptonuria to Ochronosis,
by A. E. GARROD, M.D. OXON., F.R.C.P. LOND.

(With Coloured Plate.)

A SHORT résumé of our knowledge of this rare condition and of its apparent association with alkaptonuria in some cases from the pen of Professor W. Osler appeared in THE LANCET of Jan. 2nd, 1904. A conversation with the author of that paper at the Leicester meeting of the British Medical Association in July last led to the identification of the nature of the case here reported.

The patient, a woman, aged 47 years, was admitted to the wards of the Leicester Infirmary in 1895, under the care of the late Dr. Charles Cooper. That gentleman was suffering from bad health at the time and gave me permission to make any investigations into the case I thought fit. The patient was suffering from a large ulcer on the right leg and discolouration of the skin. The ulcer had existed for 12 years and had been continuously dressed during that time with a strong carbolic lotion. The discolouration had existed for five years. No history of any similar complaint in her family could be obtained. The face was coloured a dark brown. Inside the lips were patches of blackish discolouration. The ears presented a bluish appearance. The hands also showed a bluish discolouration. (See Figs. I. and IV.) There was a small bluish-black pigmented patch on each conjunctiva (see Fig. II.) about midway between the inner canthus and iris, when the iris was central. There were signs of a cavity at the apex of the right lung and the patient was much emaciated. Her mother had suffered from pulmonary tuberculosis. The urine was almost black in colour; it gave a dark brown precipitate with liquor ferri perchloridi and a slight white precipitate with bromine water. No sugar or copper-reducing substance was present. The urine was not of the same colour every day. Gangrene of the toes came on and the patient died in a few days from exhaustion, there having been no material change in the symptoms.

Post mortem, the right lung had a dry cavity at the apex. The suprarenal bodies were hard and dark in colour. The rib cartilages were stained bluish-black; the colour was more marked in the central area than at the periphery. The cartilages of the ears were bluish-black. The intervertebral cartilages were not examined. The patches of pigment in the eyes were seen to be due to a deposit of pigment in the superficial layers of the sclerotic. The note made at the

time was that microscopically the colour of the cartilages was due to "ordinary fine granular pigment."

Diagnosis from necropsy.—Tuberculosis of lung and disease of adrenal glands (Addison's). The colour of the urine was considered to be due to carboluria.

Coloured drawings were made during life of the superficial appearances, and microscopical preparations of the skin and cartilages were made and also of the suprarenal glands. The following is a description of their present appearances by Mr. E. H. Shaw of St Bartholomew's Hospital.—

Section of ear.—The skin is normal, no pigment being seen. The cartilage is pigmented throughout its substance, the colour being darkest externally, especially in the perichondrium (Fig. V.).

Section of skin of finger.—The epithelium shows the ordinary structure and arrangement of a skin surface. There is no pigmentation of the cells of the Malpighian layer. In the true skin there are some irregular masses of fibrous tissue in the form of broad bands. These bands cross and interlace with one another and they are of a

dark-brown colour in the central part. The bands are pure fibrous tissue; no striation or nuclei are visible. The pigment is confined to these bands, it is not granular, and is evenly distributed through their substance (Fig. VI.)

Description of coloured plate.—The appearance of the patient is well shown in the illustration. The face (Fig. III.) is very dark and bears a striking resemblance to a marked case of Addison's disease. Fig. I. shows the pigmentation of the deep layers of the skin in the finger and beneath the thumb nail, and Fig. IV. that of the palmar surface of the same hand. The patch of pigment in the sclerotic is shown in Fig. II. The pigmented cartilage of the ear can be seen in Fig. III, shining through the integument. Its appearance, I believe, not exaggerated in the slightest degree. The microscopical appearance of the cartilages of the ear is shown in Fig. V. This section has been rather deeply stained with bromatoxylin and consequently the most deeply pigmented layer of cartilage (Fig. V., *s1*) appears rather lighter than the less deeply (Fig. V., *s2*), the exact opposite of its appearance in the unstained specimen. Particular attention should be paid

TABLE GIVING PARTICULARS OF ELEVEN CASES OF OCHRONOSIS.

Case	Author and reference	Sex and age	Colour of skin.	Other parts coloured	Urine colour and reactions.	Other diseases.	Length of illness.	Illustrations in report.	Microscopical details
1	Virchow: Virchow's Archiv 1866, Band xxxvii., p. 212.	M., 67	No description presumably unaltered.	All cartilages	Clear, no account of reaction	Aneurysm, ascites, hydrothorax, and arthritis deformans	?	Coloured pictures of blackened cartilages (macroscopical).	Brown colouration of ground substance, granular pigmentation of cartilage cells.
2	Boström: Virchow's Festschrift, Band II, 1891, p. 177	F., 44.	No reference.	Cartilages ebony black; also spots on valves and endocardium of heart (brownish grey)	No reference.	Strangulated umbilical hernia	?	None.	Pigment generally distributed in ground substance of cartilages, granular in cells.
3	Hansemann: Berliner Klinische Wochenschrift, 1892, Band xxix., p. 660.	M., 41	No alteration.	Cartilages of ribs, sternoclavicular, intervertebral, etc., inkly black.	Black; no reduction of copper, no homogentisic acid. Not alkaptonuria (Langstein)	General oedema and aneurysm of the left ventricle.	18 years.	None.	Langstein, Hofmeister & Beltrage, Band iv., p. 155, on Urine, also Zdzarek, ibid., p. 373.
4	Helle: Virchow's Archiv, 1900, Band cix., p. 148	F., 36.	No alteration.	Cartilages of ribs jet black, cartilages of larynx and trachea only coloured in periphery.	No notes.	Peritonitis and ruptured tubal pregnancy.	"	Microscopical appearances of cartilages and lymphatic glands.	Fine granular pigment in ground substance.
5	Ibid.	F., 62	No alteration	All cartilages.	No change	Chronic ulcer of leg and mitral valve disease.	Many years	As above.	Same as above
6	Hecker and Wolf: Festschrift des 50 Jahr Best. d. Stadt Krankenhaus zu Dresden, 1899, p. 325.	M., 73.	A dun ash colour, brownish in places.	Patch on sclerotics, all cartilages, dura mater in spots.	Brown, becoming black on standing, no sugar or albumin. Not alkaptonuria	General arteriosclerosis, softening of cerebellum, myocarditis, stenosis and inefficiency of aortic valves, arthritis deformans, and osteomalacia.	Melanuria 11 years.	None	General pigmentation of ground substance of cartilage, granular also in patches, granular in dura mater.
7	Albrecht: Zeitschrift für Heilkunde, 1902, Band xxiii., p. 365.	M., 47	During life pale (black) Post mortem, no marked pigmentation.	Rib cartilages, chordæ tendineæ of the heart	Dark, reduces copper, all reactions of alkaptonuria except homogentisic acid. Alkaptonuria	Pulmonary tubercle	"	None.	Zdzarek, ibid., p. 373, on Urine. Microscopical
8	Osler: THE LANCET, Jan. 2nd 1904, p. 10.	M., 57 Living	Coal black on the nose and cheeks, patches on sclerotics, ears blue black.	Spots on the back of the hands.	Clear when passed, becoming black on standing. Alkaptonuria	Anæmia, weak, irregular heart, and Heberden's nodules.	More than 10 years	None.	Still living
9	Ibid.	M., 49 Brother of Case 8.	Normal, patches on sclerotics.	Ears showed blue-black through the skin, no post mortem.	Alkaptonuria	Died from pneumonia	—	None.	None
10	Ogden: Zeitschrift für Physiologische Chemie, 1893.	Living	—	Pearly grey inside concha.	Alkaptonuria	"	?	"	?
11	Pope: Present case	F., 47	Face brown, patches on sclerotics	Rib cartilages blue-black, ears blue. In side of lips black patches.	Black. Not alkaptonuria or true melanuria	Chronic ulcer of leg, phthisis and sclerosis of adrenals	Five years	Superficial and microscopical appearances.	Fine granular pigment in cartilages pigment in the white elastic tissue in the skin but not in rete Malpighii.

to Fig. VI. as this is the only section of the darkly stained skin that has yet been made. If anyone will take the trouble to compare it with a section or drawing of one from a case of Addison's disease, the difference in the site of the deposited pigment will at once appear. In the present section it entirely appears in the fibrous bands (Fig. VI., *f.f.*) and to me, and possibly to others, brings to light for the first time the extent of this layer, acting as a differential stain for this tissue, while in Addison's disease it appears, as does the normal pigment in the coloured races of mankind, as a very thin deposit in the deepest layer of the rete Malpighii (*r.M.*).

This case is the eleventh reported of this disease and the first from the British Islands. I present in tabular form short abstracts of all the former cases. It will be seen that all these cases had black colouration of cartilages. Five cases had black urine and two of these were alkaptonuric. In two other cases of alkaptonuria where there are records of post-mortem appearances, reported by Fürbringer¹ and Moraczewski,² no blackening of the cartilages is mentioned. In none of the cases except the present one is there any record of abnormal appearances in the adrenals. Four cases had patches of pigment on the sclerotics. Three only had marked discolouration of the skin.

I think it clear that the condition, for it hardly amounts to a disease, is one that is associated with the degenerative period of life, for though by the mere tale of years some of the patients had hardly passed middle age they had almost without exception suffered from wasting disorders or diseases which had profoundly affected the general body metabolism. Some of the observers consider that the pigment is only deposited in tissue altered by disease. The present case does not bear this out and it has been, moreover, opposed by Heile.

It seems probable that the fibrous tissues, cartilage included, are, under conditions not at present clearly understood, able to act as a filter and to retain a certain pigment which is circulating in the blood, of the origin of which we are also ignorant. It is not likely that many cases where deep skin pigmentation or melanuria was present have escaped notice and record. In those, however, where the pigmentation is confined to the cartilage and the urine is clear such oversight is more likely to occur. It is to be hoped that any future case will be most carefully examined during life, it being most important thoroughly to determine the condition and reactions of the urine and blood. Professor Osler has suggested that as two of his cases occurred in brothers this may turn out to be a family disease. The family history, therefore, of all cases of both ochronosis and alkaptonuria should be inquired into. The fact that the present case was not entirely under my own care must be the apology for what I feel to be a somewhat imperfect record. I cannot conclude without expressing my thanks to Professor Osler for drawing my attention to the real nature of the case and to Dr. Garrod for valuable advice and bibliography. The latter has kindly written the following note which adds much to the value of the present paper.

Note on the relationship of alkaptonuria to ochronosis by Dr. GARROD—The question of the relationship of the very rare conditions ochronosis and alkaptonuria is a very interesting one. The existence of such a relationship was first suggested by Albrecht. The urine of his patient (Case 7), who had the blackening of cartilages which constitutes ochronosis, was brown when passed, darkened on standing, and reduced Fehling's solution with the aid of heat and ammoniacal solution of silver nitrate in the cold, just as an alkaptonuric urine does. However, Zdarek failed to extract from it homogentisic or uroleucic acid to the presence of which the phenomena of alkaptonuria are due. Osler has since described a pigmentation of the ears, conjunctivæ, and skin, such as was observed in Albrecht's case, in three middle-aged men (Cases 8, 9, and 10), who have long been known to be alkaptonuric; and although no opportunity has presented itself of examining their cartilages there is every reason which external indications can afford for believing that the cartilages, and at least those of the ears, are deeply pigmented and that they may rank as examples of ochronosis. On the other hand, in such accounts of necropsies on alkaptonurics as are available there is no mention of blackening of cartilages, and although alkaptonuria is a life-long condition

young subjects exhibit no surface pigmentation. In the cases of ochronosis recorded by Hansemann and by Hacker and Wolf (Cases 3 and 6) dark urine had been passed for many years. Langstein has shown that the urine of Hansemann's patient gave none of the reactions of alkaptonuria and in the case of Hacker and Wolf, as in the present case, the urine had no reducing properties, a fact which practically excludes alkaptonuria. It is most desirable that in future cases of ochronosis the fresh urine should be examined from this point of view. At present the evidence seems to show that among the few recorded cases of ochronosis in which black urine, or urine which blackened on standing, was passed, some at least were not examples of alkaptonuria. On the other hand, there are very strong grounds for believing that in later life alkaptonuric subjects tend to develop the characteristic pigmentation of cartilages; in other words, that alkaptonuria is a cause, but not the only cause, of ochronosis.

A CASE OF OPERATION ON THE VESTIBULE FOR THE RELIEF OF VERTIGO;

TOGETHER WITH A DESCRIPTION OF THE FLAP EMPLOYED IN ORDER TO OBTAIN A BETTER VIEW OF THE PARTS DURING OPERATION; WITH REMARKS ON THE HISTORY OF THE OPERATION.

BY RICHARD LAKE, F.R.O.S. ENG.,
SURGEON TO THE ROYAL EAR HOSPITAL.

THE patient, a woman, 29 years of age, had been for some time absolutely deaf on both sides. Both ears had been operated on several times for the cure of suppurative otitis, the right more frequently than the left, with an eventually successful result on the right side, but the left was still liable to relapses. She had been under my care for long periods during the past nine or ten years, although none of the operations alluded to had been performed by me. During the past four years she had suffered so severely with bilateral aural vertigo that in walking she described, as it were, a series of curves alternately to the right and left, but with a greater tendency towards the left. She was extremely anxious for relief, and it may be noted that it was this case which three or four years ago first suggested to me the possibility of relief by operation, though, being as she is the breadwinner of the family, with a father frequently out of work, she was unable to come into the hospital until the early part of last year. The question which needed elucidation was as to which side caused the greatest trouble and after due consideration it was decided to operate on the right ear, as one was under the impression that the right titubation was due to irritation of the left external semicircular canal. And inasmuch as we believe the sense of location not to be well developed in deaf-mutes one hesitated to remove the peripheral organ of equilibrium on both sides, the more so in view of the serious results this procedure has on the lower animals.

The patient was admitted into the hospital and an operation was performed on May 2nd, 1905, with the assistance of Mr R. S. Cocke and Mr W. H. Bowen. A flap was formed in the following way. A scalpel was inserted into the meatus, with its edge directed forwards and upwards in such a way that the heel of the edge of the blade lay between the tragus and the commencement of the helix, the rest of the blade being directed between the junction of the anterior and superior walls of the meatus, in which direction the meatal wall was divided down to the bone (see arrow in Fig. 1). On the knife being withdrawn the incision was carried upwards, close to the helix, until the upper border of the insertion of the concha to the head was reached; it was then carried backwards and downwards with a bold sweep, following much the same direction as is usual in a post-aural operation, but without bringing the lower part of the incision materially forward (see Fig. 1, *a*). The ear and external meatus were then rapidly dissected out and turned downwards, being, as it were, unrolled, and laid on the tissues of the neck, below the angle of the jaw, and inclosed in sterilised antiseptic gauze. This method of dealing with the ear not only

¹ Berliner Klinische Wochenschrift, 1875, Band xli.

² Centralblatt für Innere Medizin, 1896, Band xvii., p. 177.

permitted an excellent view of the parts but enabled one in working to avoid any possible injury to the meatal wall in any part. At the same time the auricle being absolutely removed from the field of operation retractors were dispensed with; also as the wound was deepened far more light was available in its deeper parts than is obtainable by other methods. If any difficulty is found in retaining the ear in the position suggested it can be kept there either by means

next step in the operation was to obtain free access to the vestibule. This was done by cutting a third hole into the vestibule, between the two described, with a burr made on the principle of a carpenter's bit, and chiselling away the small bridges of bone left between the three openings. This is done with an extremely fine chisel, highly tempered, and cut with a high pitch. The opening into the vestibule was then enlarged in every direction by means of this fine chisel

FIG. 1.

The dotted line from * to * shows the line of incision, the arrow the direction in which the meatus is divided.

of a stitch holding it to the skin under the chin or by attaching to its raw surface a pair or two of artery forceps. As a result of the previous operations the bony semicircular canal was very quickly exposed to view. By means of a small gouge the whole of its upper surface was rapidly cleared from the more porous bone immediately suprajacent (see Fig. 2). The upper surface of this external

FIG. 2.

semicircular canal was then removed by a burr until the membranous canal was opened (see Fig. 3). And it might be well to point out that the diameter of this canal does not exceed a twentieth of an inch. The canal was then followed up along its anterior and posterior limbs, posteriorly until the increase in its calibre notified the close proximity of the ampulla and anteriorly until its slightly backward direction indicated the near approach to the vestibule. For the canals are not really semicircular but rather exceed this. The

FIG. 3.

(Fig. 4). The commencement of the superior canal was freely opened and its ampulla was scraped out. It was more difficult in this case to open the posterior ampulla as the posterior canal was situated at an extremely low level, as is not infrequently the case. The canals themselves, posterior and superior, were not interfered with. The next stage in the operation consisted in freely opening the foramen ovale by abstracting the foot-plate of the stapes so that no fluids could be retained in the opened vestibule. The whole operation cavity was then cleansed with a strong antiseptic

FIG. 4.

solution and well filled with oily iodoform emulsion. The operation cavity was filled with sterilised gauze, the end of which was brought out to the meatus, and the ear replaced, the greatest care being taken to see that the helix came back into its original position. No further division of the meatal wall was made rapid healing in these cases being a desideratum and the preservation of the operation cavity not particularly desirable, as hearing in this instance had been completely lost for so long a period.

The after-history of this case was absolutely uneventful.

There was no shock, nystagmus, or vertigo. At the end of three weeks the patient was able to walk very fairly straight, to go up and down stairs, and to perform any actions she chose without any inconvenience, though she now complains that the giddiness, still present on the left side, is so severe that she wishes an operation performed on that side also. The scar is scarcely visible; there was a slight and transient facial paresis.

Remarks.—In considering the history of this operation one must refer to the stimulus given to operative work on the labyrinth of the internal ear, which originated from two special causes. The first of these causes was undoubtedly the marked relief afforded to sufferers from *tic douloureux* by the removal of the Gasserian ganglion within the skull and the second was the brilliant results which ensued when suppurative labyrinthitis was treated by correct surgical methods. Undoubtedly the first of these causes acted more directly on the general surgeon and led him to attempt the heroic operation of dividing the auditory nerve within the skull, while the second cause more directly appealed to the aural surgeon.

I shall not in this paper discuss or describe, even shortly, the various methods which have been employed for division of the auditory nerve within the skull, not on account of the high mortality which has followed these operations, but chiefly for the reason that they were all published prior to the publication of any operative work on the intact labyrinth and because it seems that we have every reason to believe that where intracranial division of the auditory nerve has been successful direct destruction of the posterior half of the membranous labyrinth would have been equally efficacious as far as vertigo is concerned; but what is of greater importance still, judging by the six published cases, the latter operation is without risk to life. Here, as elsewhere in surgery, absolute priority in publication is not a matter of any great moment. This is the more so in this instance, as priority of operation was not accompanied by priority of publication; for whilst the honour of having performed the first operation on the labyrinth in non-suppurative disease of the middle ear for the relief of vertigo belongs to Milligan,¹ the writer antedated him as far as publication is concerned.² Consequently the real credit for the initiation of operative interference with the labyrinth may be equally claimed by both. It is hardly necessary to add that I was unaware of Milligan's work at the time.

I have in this article omitted all reference to tests with regard to hearing power, though it may be taken that, as far as one can judge, in other cases the operation was justifiable, as it is quite certain that the result in each case was successful. After reviewing the published cases one is forced reluctantly to the conclusion that, while brilliant results are obtained for the relief of vertigo, yet with regard to intolerable tinnitus aurium and noises in the head, where ordinary remedies fail, judging by the results of published cases, neither intracranial nor intralabyrinthine operations promise great hope of relief.

In considering the evolution of this operation it is somewhat remarkable that Milligan's operations, of which there were three, consisted in the removal of the external canal only, leaving uninjured the ampulla, while my first operation went a step further by including the removal of all of the semicircular canal, allowing free entry into the vestibule. In all these cases severe constitutional disturbance followed, which was of some considerable duration and was marked by a temporary increase in the vertigo and by transient shock. From these cases I was led to consider that the proper method was to attack the vestibule, thereby removing the whole of the vestibular fluid and destroying the ampullary nerves and obliterating entirely the lining membrane of the vestibule.

The next step in the operative history under consideration was illustrated by a case in which I had had the misfortune to destroy the facial nerve when attacking the cochlea. This I turned to good account by removing the whole anterior wall of the vestibule and the ampullæ of the various canals. Such a case as this, however useless as a precedent, serves to demonstrate the correctness of the view which I have promulgated—viz., that it was the vestibule that should be attacked, and that the destruction of the canals themselves then becomes of secondary importance, but it is obvious that as long as the facial nerve is intact the whole of the external

wall of the vestibule cannot be readily removed as the facial nerve crosses the vestibule between the external semicircular canal above and the foramen ovale below.

The sixth operation for intolerable vertigo is the one now reported. In this case I was enabled to carry out what I believe will prove to be the correct operative procedure to follow in cases of incurable and intolerable aural vertigo. To recapitulate briefly: after exposing the bony semicircular canal its upper surface is cut away with the electric burr until the membranous canal is opened. This canal is then followed up anteriorly and posteriorly to the entrance into the vestibule. Then, by means of a small chisel, these two openings are connected by cutting away the intervening bone. Having once obtained a free entry into the vestibule the whole of its upper surface, or the vestibular roof, is rapidly removed in such a way as to expose the entrance to the posterior ampullary dilatation. All of the exposed parts of the vestibule and ampullæ are carefully curetted with a fine curette. The next step is to see that thorough drainage is afforded to the small bone-locked cavity, which is done by removing the foot-plate of the stapes. This completes the operation, the facial nerve, sheathed in bone, lying between the openings into the vestibule. In (Fig. 5) it will be seen that the widest part of

FIG. 5.

To show transverse section of vestibule (V). F.M., Facial nerve. E.S.C. and S.S.C., External and superior canals, and at z is a dotted line to show the level at which the vestibule is opened.

the labyrinth is where the opening is made, thereby enabling one to obtain the freest entry into this cavity. We have now six cases on record in all of which relief has been afforded to a symptom of considerable gravity, for patients suffering from aural vertigo are unable to go about their business with comfort and are often indeed unable to cross a street unaided.

The evolution of the operation has been marked by a steady progress, the removal of the canals alone being followed by unpleasant symptoms, whereas the bolder operation of clearing out the vestibule has not been followed by any untoward symptom whatever, the patients being up and about within a week. And it is also with a certain sense of satisfaction that, as far as I have been able to learn, this operation has been attempted nowhere beyond the confines of Great Britain.

The flap described in this case is one which I have no hesitation in recommending as a suitable means of exposing the field of operation where it is necessary to work deeply into the petrous bone, though it is scarcely a procedure that will as yet commend itself for use in the ordinary radical mastoid operation, though the freedom which one obtains by its use might certainly tempt one to employ it more widely than intralabyrinthine operations alone would permit.

Harley street, W.

ROYAL ALBERT HOSPITAL, DEVONPORT.—As a result of the special appeal issued by the committee of the Royal Albert Hospital, Devonport, the sum of £700 has been already received. The appeal states that during the past year 4299 patients were treated, of whom 798 were in-patients, the daily average number of occupied beds being 46.9. The expenditure for the past 12 months was £4536, whilst the income to be relied on was only £3200.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF SYPHILIS FOLLOWING THE BITE OF A HUMAN BEING.

By JAMES GARVIE McNAUGHTON, M.D. EDIN.,
M.R.C.P. EDIN.

A WOMAN, aged 55 years, who was sent by her medical attendant to the Throat Hospital, Manchester, for further treatment gave the following history of her symptoms. On August 11th, 1935, she was bitten on the back of the hand by a woman and a sore which required about six weeks to heal subsequently formed at the place. About five weeks after the bite spots began to appear on her body and a little later her hair began to come out.

When the patient was seen by me on Dec. 22nd the sore on the hand was quite healed, leaving a dark red scar of the size of a florin. The rash had quite disappeared but the woman was still suffering from condylomata. Her mouth showed several mucous patches, especially on the inner surface of the lips. In the larynx there was considerable infiltration of the inter-arytenoid region, with ulceration of one vocal cord. The patient is a widow; but there seemed to be no reason for believing that the disease had been contracted in any other way and her medical attendant has informed me that a primary sore developed at the seat of the bite. The comparative rarity of the communication of syphilis in this way seems to make the case worthy of record.

Manchester.

A CASE OF HEMATOCELE OF THE SPERMATIC CORD.

By W. DIXON HARTLEY, M.B., B.S. LOND., M.R.C.S. ENG.,
L.R.C.P. LOND.,

ASSISTANT MEDICAL OFFICER AT THE BOLINGBROKE HOSPITAL,
WANDSWORTH COMMON, S.W.

THE patient, who was a tall youth of average build and 20 years of age, was playing cricket on August 26th, 1935, as wicket-keeper, when a medium-paced ball struck him just above the left pubic spine. He did not feel much pain at the time and went on playing, the game not being at all delayed. About an hour afterwards he felt pain on walking and noticed that flexion of the thigh had become difficult owing to a feeling of stiffness. There was no sign of bruising but he found that there was a lump over the region of the left pubic spine. He rubbed the part regularly with embrocation but the pain was not relieved. He went to the out-patient department of the Bolingbroke Hospital on Sept. 5th, by which time the swelling over the pubic spine had subsided and some little discolouration of the skin had appeared.

On examination there was felt in the left side of the scrotum a tumour which was continuous with a considerable thickening of the spermatic cord above it. As the thickened cord was traced upwards its diameter gradually diminished but the upper limit was very indefinite, being situated about the centre of the external abdominal ring. At the upper margin of the scrotum the cord was two-thirds of an inch in diameter. It was rounded in outline and hard but it yielded slightly under the pressure of the finger. There were no signs of hernia, the thickened cord being raised on coughing. Continuous with the cord above and extending for two and a half inches downwards into the scrotum was a sausage-shaped swelling one inch in diameter, with a full rounded end, placed a quarter of an inch above the left testicle—this organ being raised half an inch higher than its fellow of the other side. In front and at the sides the scrotal tumour was rounded and perfectly smooth in outline and configuration; whilst on its posterior aspect the constituents of the cord could be left spreading over it, the vas deferens being easily traceable

throughout its extent. The tumour was firm but pliable to digital pressure. It was not transparent to transmitted light and was not reducible. It had no connexion whatever with the tunica vaginalis and there was no effusion present in the latter sac. The spermatic veins were not enlarged on either side. There was no weakness of the abdominal walls and the thickened cord was moveable from side to side. On Sept. 8th the scrotal tumour had extended further downwards and was in contact with the testicle but could be separated from it. Its lower extremity was larger, had become more flattered, and bulged into the tunica vaginalis.

The diagnosis was hæmatocele of the spermatic cord following an injury. The patient had never suffered from hernia, but his father had had an inguinal hernia all his life. The hæmorrhage in these cases seems to occur into a pre-existing sac, probably a portion of the funicular process, which has become closed at each end in the course of development. It is difficult to imagine how a diffuse hæmorrhage into the tissues of the cord could present the physical signs described above, especially the full rounded lower limit and the definite sausage-shaped tumour, as the blood in such a case would tend to gravitate still further downwards and to envelope the testicle.

ST. GEORGE'S HOSPITAL.

A CASE OF PHLEBOLITHS SIMULATING SUBCUTANEOUS FIBROUS NODULES.

(Under the care of Dr. ROLLESTON.)

A WOMAN, aged about 50 years, was admitted into St. George's Hospital under the care of Dr. H. D. Rolleston on Nov. 18th, 1935, with subacute gastritis from which she rapidly recovered. She had twice had an "ulcerated sore throat," when a child and 12 years ago, but had never had rheumatism or chorea. The joints did not show any evidence of arthritis deformans and there was no sign of von Recklinghausen's disease (generalised neurofibromatosis).

Remarks by Dr. ROLLESTON.—The point of interest in this case was the presence under the skin over both shins of numbers of discrete, small, hard, painless, moveable nodules of the size of minute shot or less; these nodules were not attached to the bone or to the skin. There was a bunch of varicose veins on the inner side of the left thigh just above the knee and some small superficial varicose veins were visible over the front of both shins, but there was no manifest continuity between these veins and the small subcutaneous nodules. No similar nodules were found elsewhere in the body. There was some doubt as to the nature of these nodules, which closely simulated the well-known transient nodules seen in the acute rheumatism of childhood and, except for the absence of tenderness, resembled the nodules sometimes found in a number of conditions summarised by Dr. G. Newton Pitt¹ and Professor R. Stockman,² such as arthritis deformans, gonorrhœal rheumatism, "chronic rheumatism," influenza, and syphilis. One of the small nodules was therefore excised under cocaine. When cut across it had to the naked eye the appearance of a calcified vessel containing some calcareous material. After the necessary decalcification it was cut, the microscopic appearances being (vide figure) those of a vein with some calcification of its walls and calcareous material occupying its lumen; there were no recognisable blood corpuscles in it. The nodule would therefore appear to be a dilated portion of a vein in which

¹ G. N. Pitt: Transactions of the Clinical Society, vol. xxvii, 1894, p. 54.

² R. Stockman: The Causes, Pathology, and Treatment of Chronic Rheumatism.

the blood had clotted and subsequently undergone calcification; in other words, of a phlebolith in a vein showing some calcification. These appearances are entirely unlike those of the rheumatic nodule as described and figured by Dr. F. J. Poynton and Dr. G. F. Still.² As bearing on the production

Section of phlebolith in a subcutaneous vein imitating a fibrous nodule. Low power. 1. Calcification of wall of the vein. 2. Calcareous material inside the vein.

of these phleboliths it may be mentioned that the patient, who had to be on her legs a good deal, had been accustomed to wear elastic stockings because she had suffered inconvenience from the varicose veins in the lower extremities. It seems probable that the firm pressure thus exerted over the bony surface of the shins first led to the formation of local dilatations and diverticula in the small subcutaneous veins, then to isolation of, and thrombosis of the blood in, these diverticula, and so eventually to the presence of the phleboliths.

For the drawing here reproduced I am much indebted to Mr. Lawrence Jones.

BRISTOL GENERAL HOSPITAL.

A CASE OF THE STOKES-ADAMS SYNDROME, WITH NECROPSY.

FOR the notes of the case we are indebted to Dr. A. Rendle Short.

A man, aged 51 years, a painter, came under treatment on August 27th, 1905, complaining of fits. There was nothing of interest in the family history. With regard to his previous history he was in perfect health till 18 months ago, when he had an attack of "influenza" and was treated in the Bristol Royal Infirmary. Since then he had suffered from headaches and giddiness. The first fit was on June 12th last. The patient denied syphilis and had not been a heavy drinker. He had never had any symptoms of lead poisoning. He had not had rheumatic fever or chorea. Last June he had six fits in one week and had been having them occasionally ever since, about one or two a week. He also suffered from giddiness and had had headaches, but not recently. There had been no vomiting and the sight was good. The patient's description of a fit was as follows. He did not know beforehand when one was coming on. He suddenly felt giddy and at once became unconscious. He did not know if he cried out or if he was convulsed. He rapidly recovered and felt perfectly well afterwards, and was not at all sleepy. He had passed urine during the fits but had not bitten his tongue. The last fit was on August 27th, when he fell and sustained a scalp wound; this was the immediate cause of his coming under treatment. He also complained of running of the left ear for several months; it

had been slight and he had paid it little attention and could give no details. He had not had a sore throat. He also complained of sciatica in the right leg and hip.

His condition on examination was as follows. The patient was a powerfully built, intelligent man. There was a superficial scalp wound on the occiput. The pulse at the wrist on the 27th when first seen was 12; on the 28th it was 20, very irregular in force and frequency, with alternately large and small beats; the tension was high and the artery was thickened. Later in the day the pulse-rate was 44. The apex beat was always the same as the pulse, but there was pulsation in the veins of the neck at the rate of about 60. The apex beat was in the nipple line, in the fifth space, and fairly forcible. As to the heart sounds, there were a soft systolic murmur at the apex and a systolic murmur at the aortic area, also heard in the neck. The auricular systole was heard as well as the ventricular. The aortic second sound was accentuated. There was no thrill and the cardiac dulness was normal. The bowels were regular, the tongue was clean, and there was no blue line on the gums. The sleep was good. The temperature was normal. There was a little discharge from the left ear. The nervous system was normal. The pupils were equal and reacted to light and to accommodation. There was no optic neuritis but the vessels were thickened. The knee-jerks were equal and normal. The urine was acid, of specific gravity 1020, and contained no albumin or sugar; the daily quantity was 28 ounces. The patient was given seven drops of tincture of nuxvomica three times a day and kept in bed. Aspirin was given for the sciatica. On the 29th the pulse at the wrist was 44; the venous pulse in the neck was 60. At 2 P.M., whilst being examined, the patient had a "fit." It began without any warning or cry. He commenced to turn his head slowly and stiffly to the right; the eyes also deviated to the right. There were no clonic spasms of the head, the eyes, or the limbs. He was quite unconscious. The face became bluer and bluer and the respirations were quick and deep. He did not pass urine. The attack lasted 30 seconds and ended by his drawing up his legs and trying to sit up. He then suddenly regained consciousness and was not in the least confused. The attack passed off with such unexpected rapidity that unfortunately the opportunity was lost to feel the pulse or to listen to the heart. On the 30th at 6.30 A.M. Dr. Short was called to see the patient. Whilst being washed he suddenly stopped breathing, became unconscious, got very blue, and died. He was quite dead when Dr. Short got to the bedside. Artificial respiration and external massage of the heart were performed but in vain.

Necropsy.—The meninges were very oedematous and the pial vessels were full. The brain was soft and watery. No neoplasm or abscess was present. The left middle ear contained granulation tissue and the drum was perforated. The mastoid antrum also contained granulations. The temporal bone was normal and the dura mater was not loosened over it. The lungs were congested. The heart was not dilated: the auriculo-ventricular openings were of normal size. The left ventricle was a little hypertrophied. The mitral valve flaps were thickened and the chordæ tendinæ were thick and shortened. The endothelium and the musculi papillares showed white fibrous patches of thickening, which were quite superficial. The aortic valves were normal but there was a patch of atheroma in the aorta just above them. The aorta was only moderately atheromatous. The coronary vessels were traced throughout but showed no atheroma or thrombosis. The heart muscle showed a few scattered patches of fibrosis not well marked. The kidneys were of normal size; the cortex was a very little diminished and the surface was slightly granular; the capsule was slightly adherent. The spleen showed fibrous capsulitis. The other organs were normal. The cerebral cortex was examined microscopically and the cells were found to be normal. The Nissl granules were normal. The aortic nerves and vessel wall were also examined microscopically, but unfortunately the material kept did not contain any ganglia. The nerves were normal; the aorta was atheromatous.

Remarks by Dr. Short.—The association of (1) attacks of unconsciousness, in which tonic though not clonic spasm took place, and (2) a slow pulse with (3) otorrhœa suggested a diagnosis between Stokes-Adams syndrome complicated by otorrhœa and abscess of the brain. The normal temperature and absence of mastoid tenderness, drowsiness, optic neuritis, or localising symptoms were against the last-named, but perhaps the most important indication was the fact that

² Poynton and Still. Transactions of the Pathological Society, vol. 1., 1899, p. 324.

the venous pulse in the neck and the ventricular and radial pulses were asynchronous owing to the characteristic "heart block" of the Stokes-Adams syndrome. It is, however, interesting to note that Gowers points out that otorrhoea may cause slowing of the pulse. The necropsy showed no adequate cause of death. The fibrosis of the heart wall was but slight, the patches on the endocardium being quite superficial. The coronary arteries were quite free throughout from any trace of thrombosis or atheroma. Not having at that time realised the importance of the auriculo-ventricular band of His in these cases I unfortunately did not submit it to microscopical examination.

ST. VINCENT'S HOSPITAL, MELBOURNE.

A CASE OF LOCALISED INTRAPERITONEAL ABSCESS, ASSOCIATED WITH A PECULIAR FIBROID THICKENING OF THE MESENTERY.

(Under the care of Mr. G. A. SYME.)

THE patient, a married woman, aged 50 years, was admitted into St. Vincent's Hospital on Oct. 25th, 1904, complaining of abdominal pain and attacks of vomiting, with progressive loss of flesh. Her illness began 12 months previously with pain in the stomach, coming on after meals. She was treated for indigestion and improved somewhat, but after a time the pain became worse and was accompanied by vomiting after eating solid food. The vomiting relieved the pain. She was then restricted to a liquid diet, but vomiting and pain came on again and she began to lose weight. Her bowels had always been regular. She had never had jaundice. The menopause occurred five years previously. There was no history of previous illness.

On admission the temperature was 100° F., the pulse-rate was 120, and the respirations were 24. The right abdomen was rather rigid and tender from the costal margin to the iliac crest. The rigidity and tenderness were most marked just above, and to the right of, the umbilicus. In this region an ill-defined swelling could be made out. She had a slight leucorrhoeal discharge, but a vaginal examination revealed no abnormality. The tongue was tremulous and rather furred. The urine was normal except for a copious deposit of urates. The patient was kept under observation for some time. The temperature remained about 100° in the evening and normal or 99° in the morning. She vomited occasionally, chiefly mucus, once tinged with blood. The swelling in the umbilical region became more distinct and seemed more elastic and doubtfully fluctuant. The tenderness became more marked.

On Nov. 10th the patient was anaesthetised with chloroform and the abdomen was opened by an incision in the midline at and below the umbilicus. A thick, inflamed mass of adherent omentum and small intestine presented. The adherent coils were carefully separated from one another and from the omentum, the whole mass being surrounded and protected by sterile gauze wet with sterile saline solution. As the adhesions were separated pus began to ooze up and was mopped up on sterile gauze. Eventually an abscess cavity was defined, walled by small intestine and its mesentery, the latter being infiltrated and thickened and the corresponding coil of bowel being purple in colour and deeply congested. The intestine was involved for an extent of nearly three feet and was resected. The mesentery was ligatured off with silk and the divided ends of the bowel were united by a continuous silk suture through all the coats and a continuous serous suture. The abdominal incision was closed with interrupted silkworm-gut sutures. The operation caused considerable shock but the patient rallied well, especially after a pint of saline solution was infused under each breast. Except for a stitch abscess she made an excellent recovery and wrote to Mr. Syme recently to say that she was perfectly well.

The removed portion was sent to the Pathological Laboratory, University of Melbourne, and the following report was received. "At intervals in the mesentery, near its attachment to the bowel, are patches which are thickened and firm to the touch. On section these patches appear fibrous with fibrous bands extending out into the fat. In some of the patches a fair-sized vessel is seen towards the centre. Nowhere are the vessels thrombosed. The larger vessels are somewhat thicker-walled than normal but this is not marked. New vessels are not very numerous. Around some

of the larger vessels in the centre organisation has occurred into fibrous tissue with elongate nuclei. At the spreading margin are numerous large cells, fibro-blastic in character, with active nuclei. Organisms were stained for specially but none discovered. The condition is a chronic inflammatory one."

Remarks by Mr. SYME.—The pathological condition in the above case was obscure and I have been unable to find any record of an exactly similar case. Mr. J. Bland-Sutton, in a paper on the Effects of Perforation of the Colon by Small Foreign Bodies, especially in Relation to Abscess of an Epiploic Appendix,¹ has reported cases of intraperitoneal abscess due to small foreign bodies which had escaped from the large intestine. It seemed a possible explanation of this case that, in similar fashion, a small foreign body might have made its way from the small intestine into the mesentery. But no such cause could be found. It is difficult to say whether the changes in the mesentery were primary or secondary to the suppuration. At the time of operation it seemed most probable that the changes were due to some thrombosis of the mesenteric vessels and for that reason it was decided to resect the bowel, which certainly looked on the verge of gangrene. The pathological report on the removed specimen, however, showed that there was no thrombosis. The long duration and relatively mild character of the symptoms were also remarkable.

Medical Societies.

LIVERPOOL MEDICAL INSTITUTION.

The Sanatorium Treatment of Consumption.

A MEETING of this society was held on Dec. 21st, 1905, Sir JAMES BARR, the President, being in the chair.

From 8 to 9 o'clock a number of clinical cases were exhibited. At 9 o'clock Dr. R. J. M. BUCHANAN and Dr. C. J. MACALISTER opened a discussion on the question, "Is the Sanatorium Treatment of Consumption Worth While?"

Dr. BUCHANAN said that in consumption as in other infective processes, some internal power was working towards recovery and much might be done by stimulating this power to action or in assisting it when inactive. In all cases of pulmonary tuberculosis, especially in the early stages, treatment was urgently called for and was usually followed by marked benefit. He pointed out the principles upon which the treatment of consumption should be based and said that these were indicated by our knowledge of etiological factors and the principles of hygienic and dietetic treatment, which were true, honest, sensible, and right, and demanded the advocacy of all true, honest, sensible, and right-minded members of the medical profession. These principles of treatment admitted of no discussion and were best carried out in a sanatorium worthy the name by a medical man who thoroughly believed in them and enforced them in a systematic and an exact manner, with the due amount of respect which their truth and importance demanded. Dr. Buchanan's personal experience of sanatorium treatment enabled him to say that he knew of no treatment so invigorating, so sensible, and so trustworthy, and which held out so much hope and encouragement, or which afforded so great a prospect of success.

Dr. MACALISTER said that his experience of sanatorium treatment had been disappointing, for although many of the cases had been sent in the early stages of the disease in nearly every instance a relapse had subsequently occurred. He commented upon the utter futility of treating the poor in sanatoriums and pointed out that those patients who subsequently died from pulmonary tuberculosis did so in much the same period as they would have done had they never been in one of these institutions. The death-rate from pulmonary tuberculosis had not diminished to any great extent since the advent of the sanatorium treatment, and judging from the figures of those who kept careful records in the pre-sanatorium days the recovery-rate and the death-rate of the disease were about the same as they were in patients treated in sanatoriums. Dr. Macalister

thought that many of the most successful sanatorium cases represented patients in whom a strong tendency to recovery existed and mentioned his experience with patients presenting this tendency. He thought that the personal factor had more to do with recovery than any special line of treatment. He advocated the construction of inexpensive buildings for sanatoriums so that more money might be devoted to the maintenance of a larger number of cases, both early and more advanced. He thought that the best way of dealing with the problem was to endeavour to prevent the disease by exercising much stringency with reference to known elements of infection and by adequate disinfection of dwellings inhabited by persons suffering from pulmonary tuberculosis.

Mr. COLIN CAMPBELL thought it unfortunate that after 10 or 12 years of sanatorium treatment facts remained so few and statistics so inconclusive or contradictory. The utmost confusion still existed as regards the classification of cases and vagueness in the reports of the various forms of cures, so called, obtained. Favourable results lay somewhere between the 60 per cent. of "economic cures" reported from Germany and three out of 38 cases reported from Heswall in which the disease was "arrested."

Dr. G. A. CRACE-CALVERT said that statistics of sanatorium results were adversely affected by the very short stay many patients made, often six weeks or less, by the kind of work to which a patient had to return, and by the surroundings, often the most unsuitable, to which patients returned. He emphasised the necessity of sending early cases to the sanatorium, for the great majority did excellently, and it was wise to send such patients to the sanatorium first and to the country afterwards, because they then early learnt how to carry out treatment and much valuable time was saved.

Dr. J. ERNEST NEVINS considered that as Poor-law authorities and other public bodies were being urged to erect sanatoriums, the phrase "worth while" should be judged from the point of view of social economy, in which case the decision would be unfavourable. Many sanatorium enthusiasts had admitted that results were unsatisfactory but the blame was thrown on the patients who were "unsuitable." The conditions necessary to make a case "suitable" were impossible for the vast majority of consumptives, and it was little or no use teaching a man a mode of life which his social circumstances would never allow him to carry out.

Dr. W. B. H. WOOD, Dr. T. R. GLYNN, Dr. A. L. MORGAN, Dr. W. B. WARRINGTON, Dr. NATHAN RAW, Dr. A. G. GULLAN, Dr. E. T. DAVIES, and the PRESIDENT also took part in the discussion.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

—A meeting of this society was held on Dec. 15th, 1905, Dr. Leonard G. Guthrie being in the chair.—Dr. J. G. Emanuel (Birmingham) opened a discussion on the Bacteriology and Pathology of Pleural Effusions. He said that serous effusions were four times as common as purulent effusions in adults, but in children they occurred in practically equal numbers. In adults a purulent effusion was often secondary to a serous one, but in children it was generally purulent from the first. Of empyemata 75 per cent. were pneumococcal and these might be either secondary to pneumonia or primary. Streptococcal empyema was rare in children but common in adults. Empyemata containing staphylococci often indicated tuberculosis. An empyema complicating a case of pulmonary tuberculosis was generally pneumococcal or streptococcal. The naked-eye appearance of the pus was not trustworthy indicator of the micro organism. There was no essential bacteriological difference between serous and purulent effusions.—Mr. J. P. Lockhart Mummery said that cases of empyema in children could be conveniently divided into two classes—namely (1) those where the infection was purely pneumococcal and (2) those where a mixed septic or tuberculous infection existed. The great majority of cases were pneumococcal and in these a free exit for the pus was all that was required; drainage for any length of time was not required, and it was often unnecessary to use a drainage-tube at all. In the other class of cases and in those where much thickening of the pleura existed good drainage was always necessary. He advised irrigation of the pleural cavity with water or salt solution in suitable cases and considered that the fatal results which have sometimes followed this practice were to be attributed to the iodine or carbolic acid solution used. He was of opinion that the after-treatment of cases of empyema in children was very important and that the thoracic movements ought not to be restricted by tight

bandages or heavy bedclothes. He advised that respiratory exercises should be used to re-expand the lung in all cases—at first expiration against resistance to enable the sound lung to expand the affected one and at a later stage regular respiratory and muscular exercises in a surgical gymnasium which should by preference be carried out in classes of several children by a skilled instructor.—Dr. G. A. Sutherland referred to the frequent absence and slight character of the symptoms in many cases of moderate pleural effusion. Breathlessness and tiredness on exertion were the commonest symptoms complained of. Coughing, pyrexia, wasting, and anemia were often present but were not diagnostic. A lemon-coloured skin and clubbing of the fingers which had developed rapidly and without cyanosis were strongly suggestive of purulent effusion.—Dr. Edmund Hobhouse (Brighton) said that acute pleurisy could be cut short and effusion prevented by active measures in the early stage, but when once effusion had fairly commenced it was very doubtful whether it could be cut short by any medical measures. Two or three different lines of treatment have been pursued by different authorities. In the first instance it was sought to reduce the quantity of fluid by increasing the fluid output and reducing the intake. With this object diuretics, diaphoretics, and purgatives were given freely and a thirst diet was adopted; but most authorities were now agreed that the results attained were by no means proportionate to the discomfort entailed. If a reasonable trial of medical measures were insufficient to reduce the effusion it would be necessary to remove the fluid by puncture.—Dr. W. J. S. Bythell said that about three years ago he was led to undertake the investigation of the bacteriology of empyema in children, and the objects at which he aimed were to determine (1) the source of infection of the pleura, (2) the species of micro-organism, and (3) the influence of the bacteriology upon the clinical features of the disease. In 40 cases of empyema occurring in children whose ages varied between 10 months and 11 years, and of whom 27 were males and 13 were females, the source of infection in over 80 per cent. was undoubtedly an acute broncho-pneumonia, in 10 per cent. it was an acute pneumococcal infection of a pre-existing pulmonary tuberculosis, and in another case it followed upon a sarcoma of the lung. In six cases the empyema appeared to be "primary." The influence of age upon the species of bacteria was well known and his result fully confirmed the great relative frequency of pneumococcus; the actual percentage in his cases was 90 alone or with streptococcus.—Dr. W. Ewart read the notes of a case under his care at the Belgrave Hospital of a boy, aged 10½ years, treated by paracentesis, by syphonage, and the admission of air into the pleural cavity, with subsequent relapse of the effusion, which was treated by intrapleural injections of adrenalin solution without paracentesis with rapid recovery.—Mr. L. S. Dudgeon said that during the last five years he had made many examinations of the fluid taken from the chest in cases of serous and purulent effusion. If the fluid was clear and the cells, either in few or large numbers, consisted entirely of lymphocytes he thought that the case might be definitely said to be tuberculous. If, on the other hand, what was described as the polynuclear phagocyte was found it could be said that the case was due to one of the pathogenic organisms. Another point, to which reference was not made, was that in one case he found a very large number of cells which showed active mitotic figures, and post mortem the child was found to have suffered from diffuse sarcoma of the chest cavity and pleura.—Mr. Arthur Edmunds said that he desired to exhibit an apparatus to demonstrate the importance in relieving empyema of making the opening into the chest sufficiently free to allow of the pus being forced out voluntarily.

ROYAL ACADEMY OF MEDICINE IN IRELAND; SECTION OF OBSTETRICS.

—A meeting of this section was held on Dec. 15th, Dr. R. D. Parefoy, the President, being in the chair.—Dr. R. C. B. Maunsell showed a Uterus removed by Wertheim's Method for Carcinoma of the Cervix. He said that he thought that the operation should be performed if possible, for he believed that the suffering was less when a patient died from a secondary growth, as in the liver, than from the primary one. The ureter had to be separated if the parametrium was to be extirpated and he thought that there was little danger of the ureter sloughing if it was not pinched in any way. He had found it somewhat difficult to carry out Wertheim's procedure—namely, to lay the finger on the ureter and pass the finger between the ureter

and the uterine vessels. The operation was rather lengthy.—Mr. E. Hastings Tweedy read a paper dealing with some points of interest in a series of 211 major operations performed by him in the Rotunda Hospital. These comprised 44 ovariectomies, nine panhysterectomies, 15 subtotal hysterectomies, 14 pyosalpingotomies, 32 ventrofixations, two anterior colpotomies, 11 salpingotomies, 15 tubal pregnancies, three ovarian resections, nine ventral hernias, seven radical operations for procidentia and one for tuberculous peritonitis, two vaginal hysterectomies for painfully retroverted uteri, two retroperitoneal sarcomata, four Caesarean sections, 18 vaginal fixations, seven abdominal myomectomies, ten vaginal myomectomies, one enterostomy, and five vaginal hysterectomies for cancer. There were eight deaths in this series—two under anaesthesia in profoundly septic patients, two in abdominal and one in vaginal hysterectomy for cancer, one after vaginal myomectomy, one after subtotal hysterectomy, and one after abdominal removal of purulent tubes. The skin wound showed some suppuration in five cases, staphylococcus albus in two, bacillus coli in one, and a diplococcus in a fourth, whilst the germ was not looked for in the fifth. Convalescence was delayed in none of these cases. Tubal disease to a greater or less extent was found in 19 of the 32 patients subjected to ventrofixation; nearly all these were sterile and an effort was made in every instance to remove the pathological state by breaking down adhesions, resecting ovaries, and opening the lumen of the tube. He believed that neither Mackenrodt nor Wertheim had succeeded in establishing their operations for cancer on a permanent basis. Mr. Tweedy dealt with his method of closing the abdomen in layers and by means of a leaden plate, and pointed out that in a recent Caesarean section, undertaken by him for the second time, no trace of silk was to be found either in the uterine or abdominal walls, nor had any adhesions formed in the neighbourhood of the scars. He described in detail the operative technique in force in the Rotunda Hospital and the simple and inexpensive design of the theatre. None of his failures were attributed to architectural deficiencies in his operating-room, which he believed to be adequate for the requirements of aseptic surgery. In its simplicity it furnished a crushing argument against the lavish expenditure so fashionable in the present day.—Dr. H. Jellett said that he agreed with Mr. Tweedy in his views on expenditure on operating theatres. He also approved of having the windows open during operations. He thought that the sterilising apparatus should be removed to some distance from the theatre as the air could at present be contaminated by it. He was inclined to think that face-masks were not really necessary if the operator took proper care of his teeth.—Dr. F. W. Kidd said he thought that many cases of sterility were due to the condition of the male. He approved of wearing masks as a certain amount of sputum was kept out of the field of operation by them.—Dr. A. J. Horne agreed that the enormous expenditure incurred in making theatres was to be deprecated. He appreciated the strict asepsis of Mr. Tweedy and suggested that the nurses also should wear masks. The fact of so many stitch abscesses having occurred showed that, no matter what care was taken, accidents would happen.—The President said that he had not made the use of indiarubber gloves a general practice. Many operators stated that their successes were not materially increased by the use of these gloves and the difficulty of manipulation was certainly increased.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—

A meeting of this society was held on Dec. 20th, 1905. Mr. T. J. Dabell, the President, being in the chair.—Mr. R. G. Hogarth showed a girl, aged 12 years, from whom he had 14 weeks previously removed a Hydatid Cyst in the Liver. Although only a small lump could be felt through the abdominal wall the left lobe of the liver was found at the operation to be enlarged enormously, reaching nearly to the umbilicus. After incision and evacuation of the numerous daughter cysts, which completely filled the mother cyst, the latter was peeled off. The liver was indurated and fibrous around the cyst and was stitched to the abdominal wound without difficulty. Drainage was provided for and bile escaped from the wound for a long time, though the wound eventually healed soundly.—Dr. H. Michie, in opening a discussion on the Treatment of Uterine Prolapse, said that it was not easy to explain why the uterus should descend in some cases and not in others. By the aid of a diagram of a transverse section of the female pelvis he demonstrated what he believed to be

the chief structures concerned in retaining the uterus in its normal position and placed them in the following order of importance: the utero-sacral ligaments, the utero-pelvic ligaments, the levatores ani muscles, the broad and round ligaments, and the perineal body. In his experience it was quite rare to meet with complete rupture of the perineum and prolapse of the uterus in the same subject. He pointed out that the uterine ligaments, though composed of the same kind of tissue, were not ligaments in quite the same sense as were the ligaments of joints, the latter being more compact, unyielding, and attached to fixed points. Since, under normal conditions the uterine ligaments, sacral and pelvic, could be quite easily felt, both from the vagina and from the inside of the pelvis, whilst in cases of pronounced prolapse these structures could not be made out at all, he considered that this was important evidence of their function; and considering that the complaint occurred for the most part in women past the prime of life, as did other forms of hernia, he believed it was due, as in these, to relaxation and attenuation of the tissues and especially of the fibrous and tendinous structures. From its comparative frequency in spinsters he did not consider that pregnancy and labour had so much to do with its production as was generally supposed. In discussing treatment, Dr. Michie said that inasmuch as worn-out tissues could not be replaced or renewed prolapse of the uterus could not be completely cured, and that it was possible only to compensate for their defects by means of pessaries or to mend them in the best available way by one or another of the many operations performed or recommended for this purpose. In his own practice he confined himself to the use of Hodge or ring pessaries as mechanical supports and for the most part to Tait's operation of extension of the perineum, with or without the removal of a greater or less extent of the vaginal walls. This operation, when well performed and modified according to circumstances, he believed to be more satisfactory than any other, and should recurrence take place, which he did not deny might happen after a longer or shorter interval, a pessary would still afford the requisite relief.—Dr. W. R. Smith dwelt on the importance of prophylactic measures in the milder cases, such as (1) rest, (2) the remedying of endometritis or any other cause of local congestion, and (3) the avoidance or reduction of anything determining downward pressure, such as tight-lacing, straining at stool, and especially chronic cough. In the matter of pessaries he thought that the combination fluid-ring pattern acted best; cup and stem pessaries were certainly very irksome. In a survey of operations recommended for the condition he passed in review perineorrhaphy, colporrhaphy (partial and complete), colectomy, and shortening the utero-sacral or round ligaments. On the whole, he favoured ventrofixation, combined with anterior or posterior colporrhaphy. In suitable cases this gave excellent results, while the risk was practically nil. Not the least important part of the treatment was the subsequent rest in bed for at least a month, especially if the stitches were taken out.—The President said that in view of the frequency of the condition any satisfactory operation would be a great boon. All pessaries were difficult to keep clean.—Dr. W. Hunter said that patients often derived great comfort from a ring pessary and failing that Napier's cup and stem gave good results. He alluded to a treatment by the injection of paraffin or quinine.—Mr. Hogarth said that repair or advancement of the perineum often made it possible to retain a pessary. Ventrofixation was not altogether satisfactory; in procidentia he thought that hysterectomy was the best operation, as it was easy and not dangerous.—Dr. R. Alderson said that he had known ventrofixation give excellent results which continued for two or three years after the operation. Silkworm-gut sutures were used and removed at the end of two weeks, while the patient kept her bed from four to six weeks.—Mr. W. Morley Willis pointed out the advantage of an intra-peritoneal shortening of the round ligaments, as distinguished from Alexander's operation, and the discussion was continued by Dr. James Watson, Dr. A. J. Sharp, Dr. S. E. Gill, and Miss Sarah Gray.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—

A meeting of this society was held on Dec. 15th, 1905. Dr. J. Lindsay Steven, the President, being in the chair.—Dr. J. H. Nicoll showed several patients from a further series of cases of Congenital Obstruction of the Pylorus treated by Operation. He said that division combined with gastro-enterostomy was the ideal operation for the affection but

that as regards the patient it was often inadmissible on account of the extreme debility generally present. In the six cases submitted an operation had been carried out by which division had been combined with a VY plastic operation on the pylorus. The cases were not shown as "cures," sufficient time not having yet elapsed to test that, but as demonstrating the low mortality of the operation. Only one of the six patients had died. Of the others four had apparently quite recovered, a period ranging from three to 12 months having elapsed since the operation.—Dr. Nicoll also showed several Prostates which had been recently removed by operation, with considerations based on an experience of 100 cases of prostatectomy. He held that the mortality-rate of prostatectomy was fairly put at 5 per cent. and was being steadily reduced. The choice of treatment, therefore, for those cases of prostatic retention not yielding to medical treatment was increasingly in favour of radical relief by operation as against regular catheterisation. He had seen no reason to alter his opinion published in 1894, that the first step in prostatectomy should be the suprapubic opening of the bladder, the operation being then completed by vesical or perineal enucleation as might be decided. He held that nothing essentially new in the technique of prostatectomy had been added during the past ten years.—Dr. G. B. Buchanan read a short paper on Scopolamine-Morphine Anaesthesia and reported four cases in which he had used it, following the method of Korff, recommended by Terrier. In none of his cases did general anaesthesia ensue and it was necessary to give a little chloroform in addition. Nevertheless, the effects of scopolamine as an adjunct to chloroform were very satisfactory. Fear and apprehension before the operation were absent, even in nervous patients; a very small quantity of chloroform was required, there was almost complete immunity to pain for the next 24 hours, and sickness was very slight. One of his cases showed marked slowness of breathing for half an hour (ten and even seven respirations per minute) but the patient was otherwise well. All the patients expressed satisfaction with the effects. Dr. Buchanan quoted a number of cases reported in various periodicals, amounting to 4245, including 408 cases of labour, and called special attention to a paper by Roith in the *Munchener Medizinische Wochenschrift*, in which amongst other points a series of deaths was recorded and discussed. Those, with three others reported by Ries in the *Annals of Surgery*, amounted to 23, all of which, however, except two or three, occurred in patients seriously disabled by disease and could not be ascribed directly to the anaesthetic. The conclusions arrived at by the most competent observers were the following. 1. That scopolamine and morphine should be employed as an adjunct to chloroform and not as a means in themselves of inducing full narcosis. 2. That pure scopolamine only should be used because hyoscine, with which it is said to be isomeric, gave uncertain and inconsistent results. 3. That small doses ($\frac{1}{16}$ th of a grain of scopolamine with $\frac{1}{4}$ th of a grain of morphine) should be injected from half an hour to an hour before operation, or if time allowed should be divided into two doses and given separately with an hour's interval between them. 4. That chloroform must be given in very small quantities, drop by drop, and should not be pushed to the point of abolishing the reflexes; that, however, constituted one of the disadvantages. Ether was much less satisfactory in that respect. 5. That special care was necessary with those suffering from diseases of the heart or kidneys, and with children. 6. That in old people the small dose of scopolamine was often sufficient to produce general narcosis without the aid of chloroform. 7. That the solutions must be freshly prepared each time and for that purpose tablets of scopolamine were now on the market.

CLINICAL SOCIETY OF MANCHESTER—A meeting of this society was held on Dec. 19th, 1905, Mr. E. T. Milner, the President, being in the chair.—Mr. E. Stannore Bishop showed several specimens and three patients illustrative of New Growths in the Sigmoid Flexure and Rectum. He specially drew attention to three points in connexion with this subject. In the first place it was found that whilst carcinoma undoubtedly attacked all parts of the large intestine, by far the largest majority of the cases occurred in the rectum. Many of the obstructive growths found in the sigmoid flexure were not carcinomatous but fibro-adenomatous and therefore innocent except for the obstruction which they produced. Two of the patients exhibited had had such growths removed from the sigmoid flexure, the bowel being re-united; one of these had been operated upon five

years before. The immediate risk to life from obstruction was the same in both carcinoma and fibro-adenoma but the ultimate results after removal were widely different. Sufficient attention had not, he believed, been directed to this peculiarity of sigmoid neoplasms. In the second place, there was an imperative necessity in all cases of obstruction from such growths for a preliminary temporary colotomy. He detailed a case under his care in which ineffective colotomy had been performed, with the course of events during and after the excision of the bowel at a later stage. The case ended fatally; it was indeed one long struggle with sepsis due to the passage of fecal material over the raw surfaces. He referred to Hupp's analysis of fatal cases, in which 50 per cent. died from sepsis, due, as Hartwell had remarked, to the infection of the parts by fecal material. He confuted the argument brought forward that such patients were unfit for two operations, showing that at the time of obstruction they were still more unfit for total resection and that colotomy instead of further weakening the patient was the one measure which allowed the possibility of recuperation. He emphasised the fact that at the time of obstruction the actual danger was not the growth at all but the accumulation of decomposed material behind it and the poisons contained therein. Other, though less important, reasons were also dwelt upon. In the third place, he showed a patient upon whom Kraskie's operation had been performed with the formation of a sacral anus. He demonstrated the disadvantages of this and suggested that in any case in which the amount of intestine requiring removal was too great to permit of the re-formation of the normal canal ending in a normal anus the operator would be wise in being either content with a simple inguinal colotomy or, should the growth be removable, in taking away the whole of the distal intestine, so that the end of the fecal tract should lie at the inguinal anus.—Dr. G. H. Lancashire read a paper on Some Skin Affections due to Pyogenic Organisms. After discussing the important question of the secondary pus infection of skin disease, some common infections primarily due to staphylococci and streptococci infection were described with their treatment. Mention was made and instances were given of other less recognised forms of pyogenic infection.

DEVON AND EXETER MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held at the Royal Devon and Exeter Hospital on Dec. 14th, 1905, Dr. J. Mortimer being in the chair.—A vote of sympathy was unanimously passed to Dr. H. Davy in his recent bereavement.—Mr. A. C. Roper showed two cases of Sarcoma of the Upper Jaw, one before and the other after operation. He showed the tumour removed in the latter case and a microscopical section was exhibited, proving the tumour to be a large round- and oval celled sarcoma.—Mr. Roper also showed a Uterus with many Fibroids which he had removed by hysterectomy.—Mr. O. E. W. Bell read reports of two cases of Strangulated Hernia where the gut was gangrenous at the time of the operation. The first case was one of femoral hernia in a man, aged 64 years. The gut was gangrenous on operation and six inches of bowel were removed and the ends were stitched together, and the patient made a complete recovery. The second case was also one of femoral hernia in a woman aged 74 years. Here on operation it was found that the bowel had been completely divided by the process of sloughing at the seat of the constriction and that one end was loose in the peritoneal cavity which was full of faeces. The bowel was resected and the ends were sutured and the peritoneum was washed out but the patient died six hours later. In neither case was there much shock or pain, nor did the patient seem seriously ill.—Dr. J. Raglan Thomas opened a discussion on Physical Degeneration. He referred largely to the interdepartmental report on this subject. He laid special stress on the following signs of physical degeneration: (1) the majority of people, both children and adults, have bad teeth; (2) few mothers were able to nurse their own children; and (3) the stature of boys in industrial schools was very inferior to that of boys in public schools. He mentioned some of the probable causes of this physical degeneration or unfitness, such as the urbanisation of rural districts, the large amount of female labour, the consumption of tinned foods and decay of home cooking, the large amount of tea-drinking, the artificial feeding of infants on bad and insufficient food and tinned milk, and the moral contamination of both boys and girls who, lacking proper occupation in the evening, were forced out into the streets. He laid special

stress on the enormous infantile mortality, which was greater than it was 60 years ago. He mentioned three societies which in different ways tried to remedy this condition of affairs—(1) the National League for Physical Education and Improvement; (2) the National Service League; and (3) the Society for Housing of the Working Classes.—Owing to the lateness of the hour the discussion on Dr. Thomas's paper was deferred to the next meeting.

Reviews and Notices of Books.

Sanitary Laws of Scotland and Principles of Public Health.
By W. J. BROCK, D.Sc., M.B. Edin., F.R.S. Edin., &c.,
Medical Officer of Health of Midlothian, &c. London
and Edinburgh: Oliver and Boyd. Small 8vo, pp. 480.
Price 7s. 6d.

THIS little volume is handsomely bound in flexible red leather, gilt-edged, and well printed, though the type of all but 120 pages is so small as rather to strain the reader's eyes, in gas light especially, the paper being, in order to keep the volume in small bulk, so thin as to be a little too transparent—which means, after all, that we cannot have large type and thick paper combined with small bulk and full contents. The work includes, verbatim or in abstract, all the statutes relating to public health which apply to Scotland, even though they are not confined to that country—such as the Rivers Pollution Prevention Acts, the Factory Acts, the Sale of Food and Drugs Acts, and the Housing of the Working Classes Acts. Most are given only in abstract, the main exception naturally being Scotland's Magna Charta of public health, the Act of 1897. Following the Acts themselves there is in an appendix a reprint of official circulars and Orders relating to them, on the same lines as those of a little volume issued by the Scottish Local Government Board. In other appendices vital statistics, food, water, air, and ventilation are dealt with; in another a synopsis is given of the requirements of the Scottish Conjoint Colleges Examining Board for the diploma in public health and a syllabus of requirements for sanitary inspectors' certificates; and still another appendix gives a digest of decisions on the sanitary laws. The scheme of the book is therefore good and most of it has been well carried out.

In some respects, however, the work is open to criticism. Concerning preventive measures in infectious diseases, attention is quite properly given to the value of hospital isolation of scarlet fever and the author states that he will quote extracts from writers who have recently given their views on the subject. All the writers quoted, however, are those who can be ranked as doubting or denying the value of such isolation and not a word is quoted on the other side. Statistics for Edinburgh are given which are interesting and, so far as they go, support the view that hospital isolation is useful, which is evidently not what the author himself thinks, but he is quite right to doubt deductions from the figures of only a limited period. Regarding the Edinburgh figures, it would have been convenient had explanation been given of such facts as that in the year 1896 there were 2185 notified cases, of which 1703 were removed to hospital, while in 1897 the cases were 2597 and only 748 went to hospital, and of the still more remarkable fact that in 1904 the number of cases treated in hospital considerably exceeded the total number notified. Regarding disinfection, it is stated at p. 323 that corrosive sublimate solution (1 part to 1000 parts of water) should have added to it 10 per cent. of chloride of sodium, but on the next page it is more reasonably stated as 10 parts, not 10 per cent. In using the same solution for a disinfecting spray it is recommended that 10 per cent. of alcohol should be added. As to vaccination, the author does not appear to know that we in England have since 1897 had the compulsory age fixed at six months

as in his own country. Wakley, not Wakely, was a coroner for Middlesex, and Russell, not Russel, was member of the Local Government Board in Scotland. Virchow's researches relating to typhoid fever in Hamburg are spoken of but it is not said where a record of these researches is to be found. Here and there, indeed, the writing is a little careless. The book contains a great deal of useful information regarding vital statistics, air and ventilation, food, drinking water, and so on, and the digest of decisions on the sanitary laws will be found valuable. Also there is an excellent index.

Hygiene. By J. LANE NOTTER, M.A., M.D. Dub., Chairman of Council and Examiner to the Royal Sanitary Institute; Examiner in Public Health to the Universities of Cambridge, Manchester, and Liverpool; Honorary Member of the Hungarian Society of Public Health, &c.; and R. H. FIRTH, Lieutenant-Colonel, Royal Army Medical Corps; Professor of Hygiene in the Royal Army Medical College; Member of the Council and Examiner to the Royal Sanitary Institute. Sixth edition. London, New York, and Bombay: Longmans, Green, and Co. 1905. Pp. 491. Price 4s. 6d.

So to write a work of this nature as to adapt it to the requirements of both professional and non-professional readers is a more serious undertaking than appears at first sight or is generally believed. Setting aside the number and variety of scientific subjects which fall within its scope, it is no easy task to determine what to omit and what to include in order to give the general but appreciative reader sound, intelligent, and untechnical knowledge of the facts and principles underlying the many-sided subject of hygiene on the one hand, while maintaining its scientific character sufficiently to fit it to take its proper place in a series of scientific manuals intended for more advanced students, on the other hand. It is but natural in such circumstances for the reader to turn to the scientific acquirements and reputation of those undertaking it as evidence of their competence to do so and to the measure of success which has followed their attempt. In these respects there is no room for misgiving in the present case. The names and recognised position of the authors are a sufficient guarantee of their competence and the fact that this is the sixth edition of their work (the first was published in 1894) sufficiently proves the success of it. It is mainly with the general laws and principles of hygiene and with the reasons which have led up to the establishment of these rather than with the enumeration of a number of details that the authors have very properly concerned themselves. But such facts and details as have any direct bearing or are illustrative of any point under discussion have not by any means been ignored or neglected. It is surprising, indeed, what an amount of relevant and readable information is comprised in some 490 pages of which the volume consists. We have gone through these and in doing so had marked many of them for reference and comment but it is not easy, nor is there any need, to do this in the space at our disposal.

We have already said enough to indicate our opinion of the nature and the value of the book. The present edition has been partly re-written and otherwise added to and revised. We may especially direct the reader's attention to the sections devoted to air, water and its chemical analysis and bacteriological examination, the ultimate disposal of refuse and excreta (remarks on land treatment and biological methods), and to Chapter VII., on infection and disinfection. In this chapter the subject of infectious diseases and infection in connexion with the micro-organisms of modern bacteriological researches and the existing views regarding immunity to disease are well and succinctly set forth. It would be hopeless to attempt to keep pace altogether with the almost daily developments and advances in practical science, nor is it the object of a book of this kind to do so. But it is only right to add that the authors of

this manual, which contains many useful formulas and diagrams, seem to have spared no pains to bring it up to date and to make it a trustworthy and valuable guide for all and an excellent introduction in particular for those who intend to enter on a more extended course of study and work in this direction.

Handbook of Physiology for Students and Practitioners of Medicine. By AUSTIN FLINT, M.D., LL.D., Professor of Physiology in Cornell University Medical College. With 247 illustrations and 16 coloured plates on Histology. New York: The Macmillan Company. 1905. Pp. 877. Price 21s. net.

Dr. Flint's name is well known as the author of several books on physiology. He has taught the subject since 1858 and this work represents his teaching as given at present in the Cornell University Medical College. Candidly, we do not think that it will "hold the field" in this country against other better and well-known text-books. There is a kind of feeling on reading it that reminds us of the old practice—condemned on high authority as unsatisfactory—viz., putting new cloth on old garments. It contains a good deal of what used to be called "physiological anatomy," a large number of the illustrations being from Sappey and Hirschfeld. This the author regards as a necessity for his students. Descriptions and "illustrations of instruments and apparatus are omitted." Of the physiology of nerve and muscle there is but little. The *Atlas of Histology* consists of 16 plates in colour, some of which are taken from Subotta's *Atlas*; the others have been reproduced by the three-colour photographic process from actual specimens, and to these are added a few from Wilson's "*Atlas*."

To the account of the blood about 14 pages are given. There are no diagrams of its spectroscopic characters, while in the composition of blood plasma the carbonic dioxide is given as in solution. Moreover, peptones are said to exist in it to the amount of 4 per 1000. In dealing with the cause of cardiac rhythm one ganglion of the frog's heart is described as placed "between the left auricle and the right ventricle" (p. 45). We are told that reflex arrest of the heart can be produced by stimulation of the cervical sympathetic. There are no tracings of blood pressure, of respiratory movements, or muscle curves; indeed, the direct results of the graphic method have practically no representation. There are but two or three "curves" of any kind in the book and these are pulse tracings, including an obsolete one by Vierordt. At the present time it seems odd to produce a text-book on physiology and one illustrated by such a large number of figures, and yet that no space is found for blood-pressure tracings and other graphic records.

The salivary glands are described as of the racemose variety. We do not find an account of the fundamental experiments of Ludwig on the secretion of saliva. The products of gastric digestion are described in very general terms. Enterokinase can hardly be called "a true proteid ferment." As to the recent work on intestinal movements, it finds no place. Each chapter is introduced by a discourse on the physiological anatomy of the organ with which it deals, and this subject, it seems to us, is far too prominent, though it is possibly necessary for the students of Cornell College. No doubt it is helpful, but much space is taken up that might be devoted to physiology proper. The cranial nerves are fully illustrated and their functions described, about 50 pages being devoted to this subject, while their functions are also illustrated by references to clinical cases. About 20 pages suffice for the spinal cord. The diagrams given to show the motor and other cortical areas hardly correspond with our most recent knowledge on this subject. As to the sympathetic system, its treatment is more anatomical than physiological and we failed to find an account of the use of nicotine in connexion with

"cell stations." Here is a curious statement: "When the sympathetic filaments distributed to a gland are divided the supply of blood is much increased and an abundant flow of the secretion follows (Bernard)," (p. 613).

A rather long chapter is devoted to embryology and it is illustrated by a number of figures, anatomical and histological. As a whole the work seems to us to deal with physiology more on anatomical than true physiological lines. No doubt here and there reference is made to certain modern advances but other advances of equal importance are conspicuous by their absence.

As to the "*Atlas*," there is a note on the technique of photomicrography in colours by Dr. Leaming, stating how the results are obtained. The author states that he is "particularly fortunate in certain objects for reproduction." The section of the stomach showing peptic cells and acid cells he believes to be unique. We do not share his opinion if he means by unique—unique in its excellence.

A Text-book of Clinical Diagnosis by Laboratory Methods. By L. NAPOLEON BOSTON, M.D., Director of the Clinical Laboratories, Medico-Chirurgical College, Philadelphia. Second edition, with 330 illustrations. London and Philadelphia: W. B. Saunders and Co. 1905. Pp. 563. Price 18s. net.

In February last we reviewed the first edition of this work and our forecast as to its merits and usefulness has been fully justified, for the author was called upon to prepare a revision of his book eight months after its publication. Slight changes have been made and 17 pages of new matter have been added at the end covering the more important advances, or at least what are claimed as advances, such as Biff's new hemoglobinometer, Ficker's reaction on the clumping of dead typhoid bacilli, Ravold's combined heat and contact test for albumin, Cammidge's test for glycerine in the urine, and Cipollino's test (December, 1904) for hydrochloric acid in the gastric contents. Where there is a multitude of tests it rather points to the supposed unsatisfactory nature of the old standards. Most of the new advances require careful control. This, of course, can be done by the wide publicity given to them by such a work as the present. We have got reconciled to the use of the word "centrifuge," but now we are presented with "turfugation," a centrifugal method depending upon the revolution of a tube-containing bar upon a twisted cord, with which a speed of 5000 revolutions a minute may be obtained, and it is, of course, an easy stage to a "torkrit." In other respects the work is substantially unchanged. The print and illustrations are excellent. The work will prove a mine of reference for the busy practitioner and at the same time it will give him a broad view of the great strides which are being made almost daily in clinical diagnostic methods.

A Manual of Surgery for Students and Practitioners. By WILLIAM ROSE, M.B., B.S. Lond., F.R.C.S. Eng., Emeritus Professor of Surgery in King's College, London, and formerly Senior Surgeon to King's College Hospital; and ALBERT CARLESS, M.S. Lond., F.R.C.S. Eng., Professor of Surgery in King's College, and Surgeon to King's College Hospital, London; Examiner in Surgery to the Victoria University of Manchester, and to the Universities of Liverpool and Leeds. Sixth edition. London: Baillière, Tindall, and Cox. 1905. Pp. 1350. Price, cloth, 21s.; flexible leather, 25s. net.

WE have on many previous occasions spoken highly of this work and the appearance of this the sixth edition merely requires that we should mention the chief changes which have been made. Modern surgical technique has had a chapter devoted to it, several chapters have been rearranged, and a new chapter has been written on the surgical aspects of gynecology. The value of the x rays in diagnosis

and treatment has received due recognition. Much of the pathological portion of the book has been rewritten by Dr. W. D'Este Emery, clinical pathologist to King's College Hospital. The book now contains 200 more pages than were in the previous edition, though the adoption of an excellent, thin, but opaque page has made the volume less bulky than it was. We hope the authors will guard against the very natural tendency to enlarge a book at every edition. We commend this issue to the attention of the student as heartily as we commended previous editions.

LIBRARY TABLE.

A Study in Nursing. By Miss A. L. PRINGLE, formerly Matron of St. Thomas's Hospital. London: Macmillan and Company. 1905. Pp. 98. Price 1s. net.—This little book is not intended to teach nursing in detail. It is a retrospect of a nurse's work which will be a useful study for her juniors. Miss Pringle says that the lessons of many masters are so mingled in these pages with the teachings of experience that she cannot always distinguish the source of what she has written. At any rate the book contains much sound advice. The headings of the chapters indicate the scope of the little work; they are: 1. What is Nursing? And who should be Nurses. 2. A Glance at the Beginning of the Present System of Nursing. 3. Fields of Nursing. 4. Organisation of the Nursing Staff in a Large Hospital: The Matron's Duties. 5. The Hospital Staff: Ward Sisters and Nurses. 6. The Night Service. 7. The Domestic Staff. 8. The Probationer's Training. 9. The Patient's Bed: The Linen Store. 10. A Study of a Nursing Staff in a Poor-Law Infirmary. Miss Pringle quotes Dr. Worcester's definition of nursing; it is one worthy of remembrance. He says: "The profession of nursing like that of medicine is an art dependent on science; but in nursing, important as is the underlying science, the art must always predominate." The tone throughout the book is excellent. The ideal person to make a good nurse is shadowed forth in the following paragraph: "The ministering angel must have her wings tied under a big apron! The least reflection shows that there must be labour and drudgery in the task of nursing; that it involves some offices that are strongly disagreeable and some of a delicate nature; and that there will be exercises for a fine intelligence and deft hands. We must start with the sincere desire to serve and the resolution to bear what is trying so quietly and cheerfully that our sick shall not know what it costs us. We shall need that true refinement which treats delicate matters simply and delicately. Sympathy and good sense must go together in their observations and actions, and the cool, soft hand must be at once tender, firm, and skilful." No nurse can read this little book without finding much to charm and to cheer her, or without improving her knowledge.

With the Abyssinians in Somaliland. By Major J. WILLES JENNINGS, D.S.O., R.A.M.C., P.M.O. of the Force, and CHRISTOPHER ADDISON, M.D. Lond., F.R.C.S. Eng., Lecturer on Anatomy, Charing Cross Hospital Medical School, who arranged the matter for publication. With a Preface by Colonel A. N. ROCKFORD, C.B., C.M.G., R.A. London: Hodder and Stoughton. 1905. Pp. 265.—This volume embodies a diary kept by Major Jennings during the expedition against the Mullah in which the Emperor Menelik undertook to assist by operations in Abyssinian Somaliland. Colonel Rockford was associated with the Emperor's troops and on this occasion was provided with a small staff. The Emperor requested the services of two British medical officers. Major Jennings was selected as the senior. The operations in the field are well described and the information which he has collected concerning the customs, religions, characteristics and folk-lore of the Abyssinians will interest

the general reader. Major Jennings, who had served for some years in the Egyptian Army, sailed from England in October, 1903, and returned to London on April 28th following. In writing of medical matters among the Abyssinians, he draws attention to the prevalence of leprosy and to the enormous number of persons who suffer from a cestode parasite which inhabits the intestinal tract and which, he says, is no doubt chiefly introduced in the half-cooked or raw beef that is so much eaten. Rheumatism, minor intestinal disorders, inflammation of the eyes and of the outer ear passages, and hysteria in women are common disorders. Dysentery is extremely rare and malaria is scarcely known in the highlands, though it prevails in the low countries. There are no general medical practitioners in Abyssinia. Each physician is a specialist but the list of his remedies is but a small one. The book is very suitably illustrated with 65 pictures from photographs taken by Major Jennings and by a map of the route which he traversed. The volume is very good reading and the portions given up to reminiscences of big game shooting and other forms of sport are attractive. The medical aspect of the book is a comparatively small one but the whole work is of considerable interest.

Landmarks and Surface Markings of the Human Body. By LOUIS BATHE RAWLING, M.B., B.C. Cantab., F.R.C.S. Eng., Assistant Surgeon, Senior Demonstrator of Anatomy, and Demonstrator of Practical Surgery at St. Bartholomew's Hospital; late Assistant Surgeon to the German Hospital, Dalston; late Hunterian Professor, Royal College of Surgeons of England, &c. With 31 illustrations. Second edition. London: H. K. Lewis. 1905. Pp. 96. Price 5s. net.—We congratulate the author on the appearance of a second edition of this work within 12 months. Opportunity has been taken of making numerous alterations and additions in the text and the illustrations have been revised and some new ones added. The surface markings of the cerebrum and lateral sinus, which we had occasion to criticise in the former edition, are now given with greater accuracy, and we notice also that Fig. 18 has been modified to show more clearly the position of the colon. The book is certainly improved in many ways and forms a concise and lucid guide to the subject of which it treats.

Whitaker's Almanack for 1906. By JOSEPH WHITAKER, F.S.A. Pp. 792. Price 2s. 6d. net. *Whitaker's Peerage for 1906.* Pp. 724. London: J. Whitaker and Sons.—The thirty eighth issue of that incomparable work, Whitaker's Almanack, reminds us of the remark which Cromwell wrote in his Bible: "Qui cessat esse melior, cessat esse bonus," for we think that it is better than ever. Not but that we miss some of the articles which have been eliminated in order to make room for others, still that is merely personal predilection. There is hardly any subject upon which the average man can desire information which he will not find treated of in the work under review, although the recent changes in the Ministry are of course not included for the very good reason that the Almanack was published in the month of November. But "Whitaker" continues to be a book which everyone must have at hand. "Whitaker's Peerage," which is also a Baronetage, Knightage, and "Companionage," is singularly compact and is full of useful information. In addition to the body of the book the introductions deal with various points concerning the Sovereign, the Regalia, the Peerage and its degrees, peers outside the House of Peers, and the vexed question as to whether or not a bishop is always to be called the Lord Bishop. The book is an admirable complement to the Almanack.

Hazell's Annual for 1906. London: Hazell, Watson, and Viney. Pp. 640. Price 3s. 6d. net.—"Hazell's Annual" differs from other books of reference which appear at the close of a year in that it is in great part retrospective, while

others are prospective. That is to say that it deals mainly with the events of the year previous to that of which the date is given on the current issue. It is certainly one of the most useful books of reference, especially for the journalist, which we know and has one markedly valuable feature in that the articles upon such thorny subjects as the fiscal question are written quite impartially. This year's issue gives the text verbatim of such important international events as the Anglo-Japanese Treaty and the Russo-Japanese Peace Treaty. There is besides an infinity of information upon the men and matters of the day.

Who's Who, 1906. Pp. 1878. Price 7s. 6d. net. *Who's Who Year Book, 1906.* Pp. 132. Price 1s. net. London: A. and O. Black.—These two works of reference were formerly issued as one volume, but the increasing size of "Who's Who" (the current issue is 62 pages larger than the issue for 1905) necessitated their separation. "Who's Who" reminds the reader forcibly of the saying of the Apostle that "one star differeth from another star in glory" and also of the astronomical fact that the number of stars of below the first and second magnitudes is considerably greater than of those contained in the two higher magnitudes. But this is what makes the book in question so useful, for here we find information about a number of persons who, but for its friendly pages, might have blushed unseen for all time and yet persons about whom information is often wanted. We ourselves owe the work a debt of gratitude, for we are constantly referring to it. The Year Book contains lists of Government officials, clubs, editors, newspapers, and magazines, and of many other persons and things. We are glad to see that the list of medical specialists which was included last year has this year been eliminated. Altogether the two books form a valuable adjunct to the reference library.

The City Diary. 1906. City Press Office, London. Price 1s., by post 1s. 3d.—This is not only a useful diary but a handy work of reference upon many matters connected especially with the City of London. The diary for 1906 is the forty-third annual edition. It is well bound and interleaved with blotting paper.

Reports and Analytical Records

FROM

THE LANCET LABORATORY.

PHYTIN.

(THE SOCIETY OF CHEMICAL INDUSTRY IN BASLE, SWITZERLAND; LONDON AGENCY, 27A, ST. MARK AT HILL, E.C.)

PHYTIN is described as the phosphorus reserve material of green plants, containing the phosphorus in organic combination. It appears to be, in fact, a compound of calcium and magnesium phosphate with oxymethylene diphosphoric acid. According to our analysis it contains at least 50 per cent. of phosphorus calculated as phosphoric acid, P_2O_5 . It contains no proteid or any appreciable amount of nitrogen in any form. It thus differs from nuclein or lecithin. On heating phytin a slight charring is observed and the ash consists of the phosphates of magnesium and lime. The ash so obtained amounts to 65 per cent. and the moisture amounts to 8 per cent. Phytin is a gritty white powder partially soluble in cold water but completely so when the water is acidulated. The cold aqueous solution gives a curdy precipitate on heating. It is stated that this peculiar form of phosphorus compound insures the assimilation of the phosphorus and hence it is regarded as of some therapeutic value in cases of imperfect metabolism or of general malnutrition.

"TABLOID" RHUBARB EXTRACT.

(MESSRS. BURROUGHS, WELLCOME, AND CO., SNOW HILL BUILDINGS, LONDON, E.C.)

Rhubarb is well known as a bitter stomachic and purgative but some importance attaches to the way in which the extract is prepared, owing to the griping tendency of certain principles. The extract of rhubarb contained in the two-grain "tabloid" is prepared by a special process. The convenience of this special administrative form of the drug, particularly for the use of children, need hardly be pointed out.

"ANTHRASOL" SOAPS.

(EDWARD COOK AND CO., SOAP WORKS, BOW, LONDON, E.)

We have no fault to find with these soaps; they are evidently prepared with great care, having regard to the purity of the soap basis and the requirements of delicate skins. The alkali and the fats are well balanced and the soaps further contain "anthrasol," which is described as a purified, pale-yellow, limpid tar from which the pitch and colouring matter have been removed, the phenolic constituents and neutral hydrocarbons of tar only remaining. Apart from its powerful antiseptic properties, anthrasol is marked by its penetrating action into the skin. We have examined four varieties of anthrasol soap—namely, toilet soap, oat-meal toilet soap, sulphur toilet and medicinal soap, and an unscented medicinal soap containing 5 per cent. of anthrasol.

HEMOGLOBIN CAPSULES.

(JULES DENOVAL AND CO., CARLTON WORKS, NEW CROSS-ROAD, LONDON, S.E.)

It is sufficient to be able to say of these capsules that they contain perfectly pure unaltered hæmoglobin. We had the opportunity of examining the hæmoglobin used for the purpose and we found that its solution in cold water gave the characteristic absorption spectrum of hæmoglobin and on boiling the solution coagulation of the albuminous constituents took place. The hæmoglobin contained just under $\frac{1}{2}$ per cent. of iron which, of course, is the normal physiological proportion.

WYCHIA WATER.

(THE WYCHIA CO., DROITWICH.)

Wychia water is described as the natural isotonic product of Droitwich brine and its composition is based upon certain physico-chemical factors concerned in the normal physiological processes taking place in the intestine. Our analysis of the water gave the following results in regard to its chief constituents per litre: common salt, 11.93 grammes; and sodium sulphate, 7.84 grammes. Beside these constituents there are present also small quantities of other natural salts, while it should be mentioned that Droitwich brine is distinctly radio-active and, in fact, gives off a gas which would appear to be the radium emanation. The water is in reality a solution of salines which are present in such proportion as to cause an increase of the true secretion from the mucous membrane of the intestine in contradistinction to the excess of fluid produced there by osmosis or irritating substances. Wychia water, therefore, in acting as a laxative, does so purely physiologically and not mechanically. In doses of from four to eight ounces two or three times a day the water has proved to be of service in habitual constipation, in relieving plethora, and in increasing the secretion of urine and eliminating uric acid. It is an efficient though not drastic saline aperient.

OZONE PAPER.

(R. HUGGINS AND CO., 199, STRAND, LONDON, W.C.)

The ozone paper consists of a bibulous paper saturated with a well-known deflagrating salt. On lighting the paper fumes are abundantly evolved which consist in reality of very finely divided particles of potassium chloride which when inhaled give some relief in certain respiratory disorders, as in asthma. The papers are very well prepared and answer uniformly. The use of the term "ozone" is open to criticism.

THE LANCET.

LONDON: SATURDAY, JANUARY 6, 1906.

Our Readers and Ourselves.

WE wish all our readers a Happy New Year. Not so long ago it was our custom in the opening number of each year to review that which had been done directly by THE LANCET for the benefit and advancement of the medical profession during the 12 months passed and at the same time to indicate in what particular direction, and by the help of whose well-informed pens, we proposed to carry on our endeavours during the year to come. The proceeding was perhaps egotistical but it had its advantages. It showed that we were ready to rely upon our readers for information as to their needs and it helped us to receive from them highly valuable criticism both as to what we had carried through in the near past and as to what we proposed to do in the immediate future. Perhaps our discontinuance of this annual insistence upon the close relation between ourselves and our readers has not been as much due to our increasing modesty as to our feeling, which ineluctably has grown stronger year by year, that our desire to serve the medical profession needs no protesting. We can appeal to a record of over 80 years, during which our single aim has been to advance the scientific and material position of our calling, as both a proof that we have deserved the confidence so freely bestowed upon us and an argument that we are likely to continue to deserve it. We are not, therefore, proposing to revert to the publishing of any general programme of intended effort or any general summary of bygone accomplishment. But we think that we may without undue *amour propre* point to two instances where our action has had unquestionable result, as a guarantee that the trust which has been for so long reposed in us will always be met by personal and active endeavour on our side.

Any service which we have been able to render to the Metropolitan Hospital Sunday Fund has always been a source of especial gratification to us. The hospitals of the greatest city of the world have for the most part had to fight hard for their existence ever since they were instituted, remembering always that for them mere existence does not suffice but must be accompanied by growth and by ever-developing usefulness. "Hospital Sunday" was, as is well known, first instituted with marked success at Birmingham, an example soon followed in other large provincial towns but not at once in London. From 1869 to 1873 THE LANCET was constant and earnest in urging the desirability of promoting a Hospital Sunday Fund for the metropolis and in the course of these years numerous and weighty articles on the subject were published in its columns, as well as a large number of letters—notably some from Mr. F. W. LOWNDES of Liverpool. As a

result of this and of other persistent and disinterested advocacy, in 1873 the Metropolitan Hospital Sunday Fund was organised to aid in the collection of the annual income indispensable to the maintenance of the London hospitals, and the Fund once started has contributed ever since an important proportion of their resources. In advocating the claims of such a Fund as this public advertisement of an intelligent character and of the widest kind is necessary in order that the needs of the institutions on behalf of which assistance is asked may be placed effectively before all who may be able to give. The pulpits of the various places of worship in the metropolitan area, and beyond it, offer a valuable means whereby the congregations assembled may be informed of what is expected of them; and THE LANCET for nearly 20 years has rendered what we trust has been practical assistance to the efforts of the preacher. That is to say, the proprietors of THE LANCET have caused to be printed at their own expense, annually (with one exception) ever since 1886, a Special Supplement in support of the Metropolitan Hospital Sunday Fund. This has contained not only the statistics of the Fund as published by the authorities of the Fund itself, but the results of independent detailed statistics of every kind from the secretaries of the hospitals in reply to our inquiries, and an exposition of the needs of the London hospitals, backed by such arguments and such additional information as from time to time have seemed most likely to prove persuasive. Our Special Supplements have been gratuitously distributed broadcast through churches, chapels, and synagogues in ever-increasing numbers; no less than 125,000 copies were printed and published in last June. They have, as we have reason to believe, proved instructive not only to worshippers and to those unable to attend Divine service but have also been of use to the preachers. They have advocated the cause of the hospitals as the great voluntary charities of London and have in particular urged that as charities pure and simple, without subsidy from State or municipality, their usefulness will best be continued and extended. Consistently with this view these supplements to THE LANCET have been themselves the gift of the proprietors of THE LANCET, no effort being made to recover the expenditure upon them by the inclusion of advertisements or by any other means. That the Metropolitan Hospital Sunday Fund, and other great funds and agencies competing in the same good work, may be able to keep up their figures and even to increase them is our most earnest wish and we are gratified to think that THE LANCET has been able to render assistance. The actual value of the work done may perhaps best be judged from the most recent statistics published in the "Classified Directory to the Metropolitan Charities" for 1906,¹ edited by Mr. F. W. HOWE. From these it is clear that at the present time the Metropolitan Hospital Sunday Fund and King Edward's Hospital Fund together furnish a full tenth part of the total yearly revenues of the charities to which they contribute.

The second subject to which we desire to draw the attention of our readers is the work of THE LANCET Relief Fund, and we do this so that they may assist any unlucky members of the medical profession to make application for help

¹ Longmans, Green, and Co.

under its scheme. THE LANCET Relief Fund is provided by the proprietors of THE LANCET for the affording of pecuniary help to registered medical practitioners or to their widows and orphans in cases of distress and emergency. The Fund has now been in existence for 17 years, so that a sum of money exceeding £5000 has been placed during that period in the hands of the Almoners for distribution. 450 cases have been relieved since its foundation. The scope of the Fund is now, we trust, well known to those who have read the reports which we have published at the beginning of each year, and to those who have sought assistance on their own behalf or in the interest of others.* It does not pretend to alleviate chronic distress, leaving this to be dealt with by organisations intended for that purpose, but it does aim at affording immediate help which, though in a sense temporary, is likely to be of permanent benefit to its recipient. Thus a man may help a lame friend over a stile when there is a reasonable prospect that he will be able to make his way in safety over level ground lying beyond the obstacle, whereas merely to place such a one in a position of temporary safety whence he will flounder into deep mire beyond will do him no lasting good and may land him in worse trouble than before. In bestowing assistance in emergency promptitude is of essential importance, and in the reports of the Almoners which are issued annually cases may be noted in which the donation sought was given within a few hours of the request being made. The Fund is now entering upon its eighteenth year, and it seems not unlikely that in 1906 its aid will be invoked at least as often and as urgently as heretofore. The distress prevalent through want of employment must necessarily affect very seriously many whose practices lie in centres where the working classes reside. Such practices also are, as a rule, those in which the medical man is least able to lay by provision against the sudden contingencies which he or his family may be called upon to face, and it is our earnest hope that the Fund may here be used in such a way as successfully to stave off unexpected and unmerited misfortune. We desire to express our appreciation of the services so willingly and so kindly rendered to the Fund as Almoners by many successive Presidents respectively of the Royal College of Physicians of London, of the Royal College of Surgeons of England, and of the General Medical Council, and by Sir HENRY PITMAN who has been the honorary auditor of the Fund from its commencement.

The Payment of Fees under the Midwives Act to Medical Men.

AS we anticipated when the Midwives Act became law considerable difficulty is being experienced in its practical working owing to the fact that no provision has been made for the payment of the fees of the medical men who may be called in under its provisions to the assistance of the attending midwife. One of the rules framed by the Central Midwives Board in accordance with the Act lays down that in certain conditions of special danger or difficulty the midwife must decline to attend alone and must advise that a registered medical practitioner be called in. As a result of

this rule cases are constantly occurring in which a medical man is called to see a patient under the care of a midwife and after perhaps the performance of some difficult and complicated obstetrical operation finds that the patient is too poor to pay him any fee. The excuse usually made is that the friends had not intended to call in a medical man and that they are unable to afford such attendance. At the present time there is no obvious way out of this difficulty. The Local Government Board has been appealed to for instruction and advice but it can only suggest that the local board of guardians might pay for the assistance required. Unfortunately, the boards of guardians do not all see their way to accept such advice and while some have consented to pay the fees of the medical men who may be called in, others have refused and have suggested that the services of the district medical officer should be obtained. It is doubtful, indeed, if the boards of guardians have the legal right to make such payments and, if they do, whether such payments will not result in the disenfranchisement of the husband of the patient. We believe, however, that such disenfranchisement would only be operative in the case of the elections to the board of guardians. Many of these patients, too, although not able to pay an adequate fee to the medical man, are not paupers and it would be wrong to treat them as such.

The matter is one of great difficulty and its only solution would seem to lie in the introduction into Parliament of a short amending Act authorising the local supervising authority to make payments to the medical men called in by midwives' advice under the Act on a scale to be agreed upon and sanctioned by the Local Government Board. If the Act is to work successfully there must be no difficulty on the part of the midwives in obtaining medical assistance when they require it, and it is of the utmost importance in the interests of the patients themselves that such assistance should be forthcoming without any undue delay. The framers of the Act apparently did not see their way to make any arrangement for the payment of these fees and rather than run the chance of wrecking the Bill they omitted all mention of payments to the medical men who might be summoned to assist the midwife, no doubt relying upon the proverbial generosity and charity of the profession. It is, however, neither logical nor just if the law practically compels the midwife to send for a medical man in certain conditions that the assistance rendered should not be adequately rewarded. There appears to be a good deal of misconception in the minds of some medical men as to who it is that really summons them in these cases. The fact that the midwife in advising that a medical man should be summoned has to fill up and to send to him a note on a prescribed form stating the reasons why she is sending for assistance seems to have led some practitioners to think that the call is an official one, emanating from the midwife, and that the local supervising authority will therefore be responsible for their fee. This is by no means the case; the medical man is summoned by the person whom the midwife has advised to send for medical assistance and therefore legally this person is responsible for the payment of the fee and there is no power at the present time to make anyone else or any local

* The usual forms of application will be published with our next issue.

supervising authority responsible for such payments. In the present conditions of things there has naturally enough been some reluctance on the part of medical men to attend such summonses and the midwives committee in Manchester has brought forward a proposal that one or two medical practitioners should be appointed in each district of the city who might be called upon to render assistance to midwives under the provisions of the Act. Such an arrangement we are sure would not work satisfactorily. The only right and proper way is for every medical man's name to be placed upon such a list unless he is unwilling to allow this to be done and instructions should be given to the midwives to send for the patient's usual medical attendant or to consult her wishes as to whom she should send for in cases where the patient has no medical attendant, whilst in cases of grave emergency the nearest medical man would, of course, be sent for. The passage through Parliament of an amending Act is, however, a matter for the future and in the meantime some arrangement must be made so that the working of the existing Act may not be impeded.

As the Local Government Board has suggested that the boards of guardians might make these payments no doubt in these circumstances such a use of the funds at their disposal would not be disallowed by the Government auditors. A further possibility is that in many cases the guardians or the local supervising authority might recover the payments from the patients' relatives, or they might advance the sum as a loan to be repaid within a certain time. There would still remain a large number of cases in which the fees could not be recovered from the patients and then the money would have to come out of the local funds. All these possible solutions of the difficulty will have to be considered when the time comes for drafting an amending Act and no doubt a plan could be adopted by which the local supervising authority—that is to say, the borough councils or the county councils—would be empowered to make such payments out of the funds over which they have control. If the profession will only unite in impressing the necessity for such an amending Act on their local Members of Parliament and on the members of the local county councils we have no doubt that an arrangement can be arrived at which will be fair to all parties and which will safeguard not only the interests of the patient when the necessity arises for her obtaining medical assistance but also those of the medical man who may be summoned to attend her.

Medical Men in Parliament.

THE near approach of a general election will necessarily turn the thoughts of many people towards ideal conceptions of the constitution of the House of Commons; conceptions in which all the great interests of the kingdom and all the varied forms of knowledge capable of being brought to bear upon the promotion of the national welfare would be proportionately and adequately represented. In an assembly so constituted it is manifest that medicine should hold a prominent place; first, by reason of its many forms of utility to the State; and secondly, by reason of the number and social position of those by whom it is practised.

The claims of the profession to increased representation will, we have no doubt, be strongly pressed by a certain number of medical practitioners, as they have been upon previous occasions of a similar kind; and, within certain limits, we have all possible sympathy with this attitude. Attention is again being called, as it has been called aforetime, to the number of lawyers among the Parliamentary candidates, to the protection which their presence in the House will afford to the legal profession, to the absence of any corresponding number of medical men, and to the slender prospect of any satisfactory medical legislation. Unfortunately—or perhaps fortunately—English institutions are seldom constructed upon any ideal basis and, as a rule, they have roughly shaped themselves into some sort of harmony with time and circumstance. The House of Commons, nominally a deliberative assembly, has been gradually converted into a party machine; and there is but little room in it for Members whose places in that machine cannot be at once specified and defined. The fulfilment of this condition implies a readiness to sacrifice individual knowledge or individual convictions at the altar of party; and therefore, of course, to sacrifice at the same time any advantages to the nation which the knowledge or the convictions might be calculated to secure. Good illustrations of this position have been furnished from time to time by the public health legislation of the country, and there is always fear lest the Government in power should consider it expedient to surrender the real and permanent interests of the country in order that the delinquents who may be their supporters may be spared inconvenience or offence. The party politician has to be “cocksure” that he is quite right and that his opponents are quite wrong; and in upholding this position it is necessary for him to be not only impervious to argument, but also, sometimes, indifferent to truth. It cannot be said that either the intellectual or the moral standards of politics are lofty ones; and it is certain that they are of a kind but slenderly compatible with either the study or the practice of science. The medical man who enters the political arena must often be called upon to throw overboard a good deal of his accustomed intellectual ballast and to depart, in many particulars, from his accustomed principles of action. Failing to adopt this course, even if he succeeds in reaching the House, he will find himself but a floating particle between contending factions, powerless to help or to hinder either; and, adopting it, he will be under the necessity of abandoning his most cherished convictions whenever they are out of harmony with the momentary requirements of his associates.

An essential and fundamental difference between the legal and the medical professions in relation to Parliament arises from the fact that to the lawyer a seat in the House of Commons is a recognised means to an end, an ordinary step in a professional career, while to the medical man, as a rule, it can be no more than an end in itself. The legal offices in the gift of the Government are numerous, important, and well paid, and they are regarded either as the lawful prizes of political adherents or as sopas by which opponents may be silenced or removed. The medical offices are less numerous, are but slenderly remunerated, and usually require either early training or special competence. A young lawyer who is a Parliamentary candidate

has usually no difficulty in selecting a party, and he often waits to test his powers in the House before he decides whether his best policy will be to become a nuisance to the Government, to be bought off with a small appointment, or a supporter, in the hope of ultimately winning one of the great prizes of his profession. In either case he has no difficulty in giving utterance to all the party watchwords upon the hustings, or in obtaining, if he be a man of sufficient promise, the active assistance of the party organisation in procuring his return. Cabinet Ministers, who had never before heard of his existence, will write him letters expressing their conviction that the welfare of the country depends upon his success; and he will for the moment be the embodied representative, it may be of "peace, retrenchment, and reform," it may be of tariff revision, it may be of British dominion over the seas, it may be of the necessity of a living wage for the officers of the army. A medical candidate would, as a rule, be less skilful in his suppression of the fact that there are two sides to every question; and hence he is likely, in the great majority of constituencies, to be rejected as a Laodicean by both parties. He will tend to dwell upon the needfulness of submission to the teachings of science; and, where science has spoken plainly, upon the vanity of the attempts at compromise which are so dear to the heart of the politician. Unless supported by strong local or family influences he has usually but slender prospect of success; and, if so supported, he has probably been guided by circumstances into other channels of activity—i.e., he is no longer a typical medical candidate. Except in the cases of the representatives of the University of London and of two of the Northern Universities the medical Members of the outgoing House of Commons have probably been indebted for their seats to influences more or less remote from their profession.

As a general rule, moreover, with possible exceptions in the cases of a few London specialists, a seat in the House of Commons is incompatible with the demands of medical practice. When the courts rise the lawyers are set free, but the physician and the surgeon are never released from duties to which the most urgent calls of the party whips would have to be rendered subordinate. Even in the cases of the specialists an all-night sitting would be a poor preparation for the duties of the following day. On all these accounts we cannot but feel that the prospect of any material increase in the number of medical Members of Parliament is not one that can be confidently entertained; and, admitting to the fullest extent how useful such Members might be under different conditions, we do not think, under those which actually exist, that their probable absence is greatly to be deplored. Suppose there were 20 medical Members, what good result, so far as the profession itself is concerned, could reasonably be expected from their presence? If they belonged to the party in power they would have been returned under pledges to give a general support to its leaders, and they could not violate these pledges in order to exert pressure in favour, say, of a measure of medical reform or of medical protection. If they belonged to the Opposition their opportunities of action would be still more restricted. If, as

would almost inevitably happen, they were divided between different sides of the House, their powerlessness would be complete; and the very worst thing that could happen to the profession, in the estimation of the public, would be that it was represented in Parliament by a few Members who desired to subordinate wider interests to professional demands. We do not wish to appear unduly optimistic, but we think, in all the circumstances of the case, that matters are best as they are. Times have somewhat changed during the last half century: individual effort counts for less and less in succeeding Governments and party calls become more exacting. When THOMAS WAKLEY, the Founder of *THE LANCET*, was able to force medical affairs upon the attention of Parliament, and to do so with successful results, he was himself a prominent Member, but he was sitting in an assembly where time was found for the expression of individual opinion. Such chances no longer occur. Amongst its Members the House of Commons has generally included medical men who were also men of light and leading, possessing the ear of the House by virtue of known learning and of proved ability, and whose speeches on questions presenting medical aspects have always carried considerable weight. There is no particular reason to suppose that the next Parliament will be less fortunate, or that the present medical Members, if from any cause they should be displaced, will not be followed by successors of similar calibre. But no great outcome can be expected of their efforts in behalf of medicine. They can only enlighten other Members and so do good work indirectly.

Annotations.

"No quid nimis."

THE NATIONAL LEAGUE FOR PHYSICAL EDUCATION AND IMPROVEMENT.

THIS league, which as we mentioned in *THE LANCET* of July 15th, 1905, p. 170, was brought formally before the public at a meeting at the Mansion House on June 28th, has since been making steady progress and is now legally incorporated. The first meeting of the council since its incorporation was held at Denison House, Vauxhall Bridge-road, on Dec. 28th, 1905, under the presidency of the Bishop of Ripon who is chairman of the council, the business being chiefly of a formal character preparatory to the actual work of the league. The league has just received the generous gift of £250 which was bequeathed to it by the late Mr. E. M. Denny who was much interested in its objects and whose wishes in regard to this gift have been carried out by his sons. The objects of the league are more especially (1) to save the babies; (2) to help the children; and (3) to train the youth, although it is intended also to teach parents, to improve dwellings, and to lessen drunkenness. The league is not intended to take the place of any agencies already existing for the physical welfare of the people but to bring them into relation with each other, to help them to coöperate, and to establish agencies where none exist at present. To describe in detail how it is intended to obtain these objects would occupy too much space but we may say shortly that the intention is to bring into relationship those who are already working at different methods of lessening infant mortality, whether it be by feeding the mothers, by the supply of pure milk,

by personal visitation of homes, by provision of crèches, or by offering premiums to babies on the first anniversaries of their birthdays. By this means it is hoped to find out the best methods and then to extend them to other places where no such methods exist. In the same way the league intends to obtain coöperation between the various societies and individuals who are interested in the medical inspection of children in schools, the best forms of physical exercise, the hours of sleep, the provision of playgrounds, the establishment of boys' brigades, of holiday schools, of schools for cookery, feeding of children, and everything that tends to help the children or to train the youth. In the pursuit of all these objects, as well as in teaching parents, improving accommodation, and increasing sobriety, the league hopes to have the aid of all sorts and conditions of men, women, and children. But its chief dependence will be upon medical men, teachers, clergymen, benevolent corporations and individuals, and last, but not least, on the personal aid of women who will devote their time and energies to the help of feeble mothers and perishing infants. We feel sure that such an enterprise will not lack that support from medical men throughout the country which it well deserves. Any information which they may desire regarding it may be obtained on application to the Secretary, 49-50, Denison House, Vauxhall Bridge-road, London.

THE HOURS OF SLEEP AT PUBLIC SCHOOLS.

It will be remembered that in THE LANCET of July 15th, 1905, we published a paper by Dr. T. D. Acland containing the results of an inquiry into the Hours of Sleep at Public Schools and in a leading article in the same issue we expressed our opinion that at present we err on the side of a deficient allowance of sleep. In the Times of Dec. 20th a letter appeared signed by 15 medical men every one of whom could speak with authority upon the same subject. This letter has produced some singularly interesting correspondence in reply from both parents and schoolmasters. One of these, signed T. E. Page, is so amazing in its argument that it deserves special comment. Mr. Page is a master at Charterhouse and is a brilliant scholar but his views upon the duties of an *informer querorum* are remarkable. He says: "The one patent fact in public school training at the present time is that too much attention is paid to the body and too little to the mind." He goes on to say that schoolmasters can be justly accused of rearing mental dwarfs, and for this, "next to our own incapacity, medical men are chiefly to blame." Further, "men who ought chiefly to be teachers are so fretted and harassed about questions of physical well-being that they are driven to neglect their proper work." He agrees with the signatories of the letter from medical men to which we have referred above that want of sleep is a definite factor in the causation of intellectual inefficiency but he also considers that there are other factors a hundred-fold more important. To advise headmasters to see that boys have more sleep "is after all but a quack remedy. Headmasters and all masters already give their 'serious attention' far too largely to such poor subjects." The opinions here expressed receive a deserved snubbing in a letter in the Times of Dec. 27th from another public schoolmaster, Mr. R. F. Cholmeley of St. Paul's School. This writer points out that the question of how much sleep boys should have is surely not one to which a house master can be indifferent and that the question of how to secure it to them is not outside his practice. If questions of physical well-being harass him so that he cannot teach, "is it so certain that he ought chiefly to be a teacher?" Mr. Cholmeley concludes by saying that he hopes that one day the discovery may be made "that the proper work of a house master may be a good deal more than can be

managed in the spare time of a hard-worked teacher." We need not labour these points, but as members of that profession which apparently acts the part of the Erinyes to Mr. Page's Orestes we wish to impress upon him that a boy who does not get enough sleep will never be able to profit by instruction upon the mysteries of the enclitic $\gamma\epsilon$ or even upon more important matters. Mr. Cholmeley, we think, has put his finger upon the weak spot in modern school polity, for in many ways it would be very desirable that the duties of house master and teacher should be separate. In former days this was the custom and relics of it remained up to some 30 years ago at Eton where there were at least two "dames" who did no teaching whatever but simply acted as housekeepers. The organisation of a house containing some 30 boys is no slight task and it is too much to ask that one man should be responsible for feeding, hygiene, and other matters of domestic polity and at the same time teach both in school and out of school, and look over copies of verse and prose, and direct his pupils in their studies. But that no boy should have less than nine hours of undisturbed sleep out of the 24 should be laid down as a canon.

THE CONGRESS OF CAPITALS.

THE somewhat adventurous proposal made by Sir Edwin Cornwall will, of course, meet with the verbal approval which generally greets suggestions that are right in principle. Nobody can deny that if representatives of the capitals of the civilised world could meet periodically and compare notes in regard to the technical work on which they are engaged mutual instruction of a useful character would be imparted. The greater portion of these technicalities would relate to matters that affect public health, either directly or indirectly. Therefore we have every reason to support the proposed Congress of Capitals and to wish it every success. It is just because we do desire that the project should be realised that we must not ignore the difficulties which have to be overcome. The complexity of the political situations in the various countries undoubtedly constitutes a great obstacle. It is true that even the London County Council is political, the Progressives being generally taken to be Liberals and the Moderates to be Conservatives; but that is a mere trifle when compared to the party divisions on the continent. Then there are municipal councils that are elected by the citizens which they govern and others that are not elected but are imposed upon the people by more or less autocratic Governments. All these disparate and antagonistic elements will require very diplomatic and skilful handling if anything like harmony is to prevail. On the other hand, if such obstacles can be overcome this will redound greatly to the honour of the object or cause capable of effecting union where there prevail so many opposing interests. Indeed, one of the good results of the visit of the Paris municipal councillors to London a short time ago was that the harmony between Paris and London overcame for the time being the causes of quarrels prevailing in Paris and in London. Such appeasement, even if only momentary, must facilitate the work of administration. For instance, a project is brought forward, say a scheme for drainage, and we may mention as a case in point the sewers of Marseilles. This scheme was promoted a few years ago by the Right and Centre of the Marseilles municipal council. Thereupon the Extreme Left from political motives made a point of opposing the scheme. But none of these councillors had any personal experience in drainage; they had never lived in towns that are drained. If, however, they had all visited London, which is drained in a manner somewhat similar to that which was proposed for Marseilles, surely, in face of the *fait accompli*, the Marseilles municipal councillors would have found it much

easier to form an opinion on the merits of the scheme. By means of international congresses municipal councillors will often see in other countries that schemes about which at home they are only quarrelling have already been realised and are in working order. This should facilitate the wider adoption of such schemes and thus bring about needed improvements more rapidly. That the Congress of Capitals will be political in the sense that it will help to promote peace between nations is universally admitted. To this extent politics will be allowed and welcomed. Will the desire to achieve progress in practical matters of municipal administration be strong enough to exclude other political questions about which no such unanimity of opinion exists? Then many municipal questions are also political questions, such as education, the control of the police, sanitary and factory laws, municipal enterprise, and the expropriation of owners of insanitary areas. All these and many other questions go to the very root of the great economical and political problems of the day. Thus, while we are most desirous to see the best possible technical work done and technical problems discussed and decided on their technical merits quite apart from politics, and especially party politics, still there is no disguising the immense difficulties in the way of any such pacific achievement. Perhaps the chief merit of Sir Edwin Cornwall's proposal is that at an international congress the municipal councillors will exercise greater control over themselves. Under such restraint they might then debate on its own merits a question which at home could not be broached without causing a party fight of so fierce a character as to obliterate altogether the real question at issue. A Congress of Capitals might thus result in not only promoting the cause of international peace but might also help in mitigating the virulence of local disputes.

ROYAL COLLEGE OF SURGEONS OF ENGLAND: A NEW MEDICAL SCHOLARSHIP.

THE Royal College of Surgeons has issued the regulations relating to the Begley studentship in surgery and anatomy. This studentship, which is tenable for three years, has been established by funds left for that purpose by the late Mrs. Jane Begley of Hammersmith, wife of the late Dr. William Chapman Begley who died in April, 1887, at the advanced age of 84 years. The establishment of the scholarship is intended as a tribute to the memory of Dr. Begley. He was born in 1803 at Dun Cormac, New Ross, Wexford. The early loss of his father threw upon him the care of a mother and two sisters, but in spite of straitened circumstances he pursued an arts course at Trinity College, Dublin, and obtained the degree of M.A. He subsequently studied medicine and proceeded to the degree of M.D. In addition to this qualification he obtained the diploma of M.B.O.S. Eng. in 1830 and in 1872 was elected F.R.C.P. Lond. Dr. Begley will chiefly be remembered by his connexion with the Hanwell Asylum where he spent 34 years of his life in charge of the male department. During this long period of service his utmost endeavours were exerted to advance the usefulness of his position and to add to the improvements of this great institution. But he laid the foundation of his surgical skill in Derbyshire, where he had a large practice, the result of being in medical charge of a cotton factory. The factory was afterwards burnt out and the owner was ruined, hence Dr. Begley's removal to London and his appointment at Hanwell. Failing health prevented him writing his experiences at Hanwell, which is much to be regretted as he had a very extensive knowledge of mental disorders. The regulations relating to the Begley studentship specify that the studentship will consist of the dividends (£20 per annum) derived from the Begley bequest, and will be tenable for three years. The studentship will be awarded in April,

1906, and thereafter triennially, or at such time as any studentship may become vacant. It will be open, on the occasion of the first award, to any candidate admitted to the second examination of the Conjoint Examining Board in England held in April, 1906, and will be awarded to the candidate obtaining the highest number of marks in the anatomical part of the examination. If two or more candidates in the anatomical part of the examination shall obtain an equal number of marks, being with respect to the other candidates the highest number of marks obtained by any candidate, references shall be made to the marks obtained by them respectively in the physiological part of the examination and on the combined result the adjudication shall be made, and if their marks shall still be equal it shall be open to the two senior examiners in anatomy appointed by the Royal College of Surgeons to call upon such candidates to present themselves for further examination or to take such steps as may enable them to adjudicate in the matter. The stipend will be paid yearly and the student will receive the first instalment within three months after the award of the studentship and will be required, before payment of the second and third instalments respectively, to send to the secretary of the College a certificate from the dean of his medical school to the effect that his conduct has been satisfactory and that he has been applying himself diligently to his studies.

A MUNICIPAL MILK DEPÔT FOR LAMBETH.

ON July 14th, 1904, the Lambeth borough council decided to establish and to maintain within the borough a milk depôt for the distribution and sale, at a nominal charge, of specially and suitably prepared or modified wholesome cows' milk for the use of infants whose mothers are unable to suckle them wholly or in part. The depôt, which is situated at 66, York-road, Westminster Bridge-road, S.E., was opened on Jan. 1st and every effort will be made by enlisting the help of the clergy, medical men, guardians of the poor, district visitors, and the like to insure that the benefits of the depôt are confined to deserving cases. The premises are fitted up with strict attention to hygienic requirements and the milk is to come from a farm in Hampshire which is to be under medical and veterinary supervision. The milk is guaranteed to be up to Government standard and the cream is to contain not less than 50 per cent. of butter fat. On arrival at the depôt the milk is filtered, cooled, "humanised," and after pasteurization is stored in special bottles, each bottle holding just enough for one meal. The charges are 3d. daily for an infant under six months of age and 4d. daily for infants over six months up to 12 months. A slightly higher charge is made for persons living outside the borough. Female sanitary inspectors are to be told off to visit the infants and arrangements have been made for the weekly weighing of infants under the supervision of the medical officer of health. A table of simple instructions is given to all parents or guardians who use the milk depôt. There is one very interesting underlined paragraph in the official circular which runs as follows:—

The Council realise strongly that no artificial (or hand) feeding of infants can, in any way, compare with natural feeding (or suckling), and instructions have been given to insure that the Depôt milk shall not be improperly used, e.g., by mothers who are capable of properly and efficiently suckling their offspring, but who simply, for some reason or other, refuse so to do.

This is an admirable regulation in theory but we do not envy the task of an inspector, whether male or female, who has to decide whether or not a Lambeth mother is capable of suckling her child but simply refuses to do so. The system of municipal milk depôts is an excellent one. If it be impossible, as it seems at present, to insure that all town dwellers shall have a sufficiency of sleeping room, together with a proper supply of sunshine and of air, it is nevertheless

quite feasible to insure that they shall not be supplied with adulterated or impure milk. Perhaps the Lambeth council will now make it incumbent upon all purveyors of milk to declare openly that the milk sold by them contains preservatives, should it do so, together with the nature of the preservative and the amount thereof. If preservatives are harmful, and there is doubtless a difference of opinion on the matter, the public should by all means know the fact. If preservatives are not harmful, and in the opinion of milk vendors they are not, and the public like them, then there can be no harm in the public knowing that they are used. We think that the Lambeth borough council is to be congratulated on its new departure, although it has taken a long time to carry out its decision. The scheme will, of course, mean an additional charge on the rates, for hardly any municipal undertaking in London is ever profitable or even self-supporting, but if the appalling infantile mortality of 151 per 1000 can be brought down Lambeth may congratulate itself. We see that the depot is not to be open on Sundays but there is no intimation as to whether a double supply will be given out on the Saturday or whether infants will have to do without municipal milk from Saturday to Monday.

TYPHOID EPIDURAL ABSCESS.

It is now well recognised that the typhoid bacillus may remain in the system after recovery from typhoid fever and give rise to abscess in various parts, particularly in the bones. At the meeting of the Société Médicale des Hôpitaux of Paris on Nov. 17th M. F. Raymond and M. J. A. Sicard reported a case in which suppuration took place in a situation in which it does not appear to have been observed previously—the epidural space of the lumbar region. A man, aged 48 years, contracted typhoid fever in January, 1905. During convalescence, at the beginning of March, he felt severe pains in the right hypochondrium, right iliac fossa, and right leg. The iliac fossa was puffy. Progressively the leg became paralysed and the symptoms, sensory and motor, appeared on the opposite side. In May, two and a half months after the onset of the paralysis, there were almost complete paraplegia and paroxysms of pain of intense severity. The legs atrophied and the reaction of degeneration was obtained in the quadriceps and adductors of the right thigh. In the area supplied by the crural nerve hyperæsthesia was found at some times and hypo-æsthesia at others. The sphincters were little affected. The knee-jerks and tendo Achillis reflexes were absent. There was no clonus and Babinski's sign was not present. No particularly painful spot could be found in the lumbosacral region. The temperature ranged irregularly between 98·6° and 101·3° F. As the onset of the symptoms had been marked by swelling and puffiness in the neighbourhood of McBurney's point, extension of disease to the cord by the medium of the lumbar plexus from an infectious appendicular focus (the meta-typhoid appendicitis of Dieulafoy) was suspected. M. Raymond and M. Guillaïn have published a case of ascending neuritis of the lumbar plexus after appendicitis. Although all the symptoms seemed to point to ascending neuritis and consecutive myelitis it was decided to obtain further information by lumbar puncture. To the great surprise of M. Raymond and M. Sicard, as soon as the needle penetrated the ligament between the third and fourth lumbar vertebrae and entered the epidural space drops of pus began to flow. The typhoid bacillus was found in the pus. On the following day laminectomy of the third and fourth lumbar vertebrae was performed and half a spoonful of pus mixed with blood escaped from the epidural space. The laminæ removed were found to be quite sound. During the operation some cerebro-spinal fluid was removed with a Pravaz syringe. It was clear and devoid of cells. The wound was drained,

good recovery ensued, and the symptoms gradually disappeared. At the time of the report all that remained was slight rigidity of the spine. Thus the typhoid bacillus became located in the fatty and cellular tissue which fills the epidural space and there produced suppuration.

THE WINTER EXHIBITION OF THE ROYAL ACADEMY.

THE winter exhibition of the Royal Academy which was opened to the public on Jan. 1st is a notable exemplification of the saying, Time brings its revenges. A large number of the pictures exhibited are by masters who during their lifetime were, from the Academy point of view, outside the pale. Burne-Jones, Alfred Hunt, Rossetti, and Simeon Solomon occupy a large space upon the walls and their works form a by no means inconsiderable portion of a collection of extraordinary interest. From our own purely professional point of view the chief picture in the exhibition is the fine portrait of Dr. John Ash by Reynolds. This picture, which is lent by the Birmingham General Hospital which owes its foundation to Ash, was painted in 1788 and represents Ash in his doctor's gown, wearing a black velvet suit and a wig. He is seated in a chair holding a plan of the hospital, the buildings of which appear in the background. Ash was born in 1723 and educated at Trinity College, Oxford, whence he graduated as M.D. in 1754. He settled in Birmingham and soon acquired a large practice. When at the height of his fame he became melancholic and had to be separated from his family. According to Munk,¹ he recovered his mental balance by means of the study of Euclid. Anyway, he did recover and resumed practice with great success in London in 1787. In the same year he was admitted a Fellow of the Royal College of Physicians in which body he held many offices. He died in 1798. Of the other works in the exhibition there are fine examples by Turner, Hogarth, R. Wilson, de Wint, Romney, Linnell, Van Dyck, Frans Hals, and many others. Altogether it is a very noteworthy exhibition and is small enough to be seen with comfort.

MEDICAL MATTERS IN LONDON ELEMENTARY SCHOOLS.

THE report of "The Medical Officer (Education)" for the year ending March 31st, 1905, was submitted by the education committee to the London County Council on Dec. 13th, 1905, and now lies before us. The report has a much wider bearing than would appear from the date which it bears, for it contains the substance of Dr. J. Kerr's two preceding reports made to the late London School Board. Previously to the London School Board there had been no such reports, so that from a medical point of view only statistics dealing with the last three years are available, which is much too short a period of time whereon to found any dogmas as regards school hygiene and the like. The report now before us deals very fully with the physical conditions of child life in London, especially as regards mental activity and educational fitness or unfitness. In 1903 a scheme was put forward for an inquiry into the relations between (1) educational status; (2) the physical condition; and (3) the social condition of about 50,000 London school children. Cost, however, stood in the way and even a more modest scheme, "which would not cost more than £300, has been felt to be inopportune and at present is in abeyance." Dr. Kerr considers that an inquiry ought to be carried out, for, as he says, "the vitality statistics of those who are about to enter on active service in the affairs of life, and whose energy is the chief of the national assets, is surely worth the cost of collection." We quite agree with him but the money should be found by the State and not by the ratepayers.

¹ Roll of the Royal College of Physicians of London, vol. II., p. 378.

A beginning, however, has been made by two medical practitioners—namely, Dr. Frances May Dickinson Berry who examined into the conditions of 1612 girls, and Dr. O. J. Thomas who examined 1861 boys coming generally from the same districts. The results of this inquiry may be shortly summarised as showing that poverty, exemplified by want of clothing, personal uncleanness, and bad housing, distinctly affects for the worse physique as expressed in terms of height and weight. Overcrowding—i.e., living more than five in one room—produces startling effects, of which tables are given. Out of ten children coming from families living more than five in one room, all except one were markedly deficient in height and weight, although, curiously enough, their mental activity was on the whole good. Statistics are given of one family where five children and the father all lived in one room. There were three girls, aged respectively 22, 16, and 15 years, and two boys, aged respectively 18 and 9 years. In such circumstances as these how can we expect to find even the most elementary regulations of morality, decency, or self-respect attended to? As regards the age of school attendance, Dr. Kerr is in favour of school for infants, if they are properly taught, as up to now they have not been, "but this is being amended." The provision of crèches is recommended, supposing that the difficulty of finding the money can be got over. The remainder of the report deals mainly with the question of infectious diseases in relation to school attendance and with matters such as vision, hearing, special schools, the lighting, heating, and ventilation of school buildings, and with school hygiene. An appendix by Dr. Thomas deals with an inquiry conducted by himself, in conjunction with Dr. S. Davies, into the outbreak of measles in the Woolwich district which commenced in 1904. In a large number of instances infection was not contracted at school but at home. A list of ten general conclusions to which Dr. Thomas and his colleague have come, "as a whole up to the present," is given. The whole report is of great interest and importance and we hope to deal with the matter therein contained at greater length in a future issue.

SUNLIGHT IN 1905.

THE first thing noticeable in glancing at the table which follows is the large amount of sunshine enjoyed during the year at some stations compared with others in the same region. It is observed, for instance, that in the south, Bournemouth, Torquay, and Hastings were considerably more sunny than the other places and that Southampton, which is some distance from the sea, had less sun than all. This illustrates a rule that is general in these islands, where there is almost always more sunshine on the coast than inland. It does not at all follow, however, that the three resorts so favoured by 1905 will be in the same prominent position at the end of 1906, for the average number of hours is nearly the same all along the south coast. In the western group Blackpool was the brightest and that resort was closely followed by Tenby, and Douglas, Isle of Man. Among the resorts on the east coast of Great Britain there is one spot that stands far above the others. This is Lowestoft, the most eastern part of the kingdom. Its grand total of 1827 hours was not only larger than that at any other place in its vicinity but also larger than at any of those on the other coasts. Taking an average of the past 25 years, however, there is slightly more sunshine on the south coast than on the coast of East Anglia, but last year the important months of April and June were wet and dull in the south of England, while the contribution of August was also less than usual. Among the inland stations it is somewhat surprising to see that Bath received less sunshine than northern Harrogate and it is not often that the Glasgow aggregate

exceeds that at Manchester. The Channel Islands possess the highest average sunshine, but during last year the deficit was very great, 211 hours at Jersey. The brightest spot relative to its average was Blackpool, where the excess was no less than 398 hours.

Sunshine in 1905.

Station.	No. of hours.	Station.	No. of hours.

THE EXPLANATION OF PULSATING EMPYEMA.

THE phenomenon of pulsating empyema or pulsating pleurisy (for the fluid though usually is not necessarily purulent) has always excited considerable interest and many theories have been advanced to explain it. In the *American Journal of the Medical Sciences* for November Dr. W. J. Calvert has published an important paper on the subject and has brought forward an entirely new theory of the pulsation for which he gives good reasons. In 1872 Traube expressed the opinion that the pulsations were due to pericardial effusion associated with the empyema. But in 1875 Frentzel denied that pericardial effusion was necessary for the pulsation. In 1881 Comby explained the pulsation as follows: "When the lung is completely collapsed, pushed to one side, and adherent to the pericardium it no longer resists the heart, the pulsations of which are then transmitted to the fluid in the pleural cavity, thence to the thoracic wall." In 1884 Fereol reported a case of pyopneumothorax pulsans and said that the pulsations were due to the presence of air. Kussmaul explains the pulsation as follows: "When the pleural wall next to the heart is thick enough to resist the impulse of the heart, the heart-beat is transmitted through the pleural wall to the fluid." None of these theories appear to be very satisfactory. It will be observed that in all the pulsations are supposed to be transmitted from the heart. To Dr. Calvert belongs the merit of suggesting a new and unsuspected source of the pulsations—the thoracic aorta—and giving a more satisfactory explanation of the phenomenon. While he was working on cross sections of a body in which there was left pleurisy the anatomical relations of the organs suggested to him the following explanation of pulsating empyema. The requirements for such pulsation are a strongly pulsating organ, contact of the pleural wall with this organ, distension of the pleural sac with fluid, air, or solid material, and a collapsed condition of the lung. The first condition is fulfilled by the thoracic aorta; the second by the normal relation of the pleura to the thoracic aorta; the third by the presence of fluid pus or fluid and air in the pleural sac; and the fourth by the collapsed condition of the lung in pleurisy and empyema. The thoracic aorta above lies slightly to the left of the bodies of the vertebrae; below it is almost in the median

line. Immediately over the aorta is the parietal pleura from the fourth or fifth rib to the diaphragm. In the normal thorax the aortic pulsations are absorbed by the compressible lung tissue and consequently are not transmitted. Fluid in the pleural cavity compresses the lung. As it increases the thoracic walls and mediastinum are pushed outwards from the pleural cavity. As long as the lung contains air it is capable of absorbing the aortic pulsations. Finally it becomes completely collapsed and at the same time the fluid in the pleura increases and presses on the intercostal spaces and in consequence of its increased tension becomes capable of transmitting the aortic pulsations. The diaphragm also probably has pulsations communicated to it but these are absorbed by the abdominal organs. As the pulsation entirely depends on hydraulic principles the nature of the fluid is not important. However, few cases of pulsating serous effusions have been recorded. In certain cases, when part of the fluid has been withdrawn the pulsation has been observed to cease—a fact which accords with the explanation given. In the majority of cases of pulsating empyema the left side is affected. Examination of transverse sections of the thorax shows that the right pleura when distended may be pushed against the aorta. Hence the explanation of those rare cases of pulsation on the right side.

THE WINES OF THE GIRONDE, WITH ESPECIAL REFERENCE TO CLARET.

UNDER the above heading we hope to publish in an early number the report of our Special Commissioner who was appointed by us a few months ago to visit the claret-producing districts of France during the last vintage. The investigation is now completed and the report will give an account of the processes involved in the production of claret and will include the analyses of typical clarets selected on the spot by our Commissioner, which will be compared with similar analyses made of clarets purchased in the open market in this country. The question as to whether, on the whole, the supply of Bordeaux wines may or may not be trusted will be discussed in proper sequence. Further, a section of the report will deal with the light natural clarets of France considered from a dietetic point of view, and incidentally the sociological aspects of the present habits of the nation in regard to its choice of an alcoholic beverage will be discussed.

SIGHING, GROANING, AND MOANING.

It is a well-known physiological rule, often enforced by the late Mr. Herbert Spencer, that all forms of psychological emotion aroused beyond a certain pitch vent themselves in physical expression. On two recent occasions we have considered in THE LANCET certain common phenomena which are the respiratory expression of abnormal nervous functions resulting in the sudden activity of the diaphragm associated usually with some degree of vocalisation.¹ Sobbing, sighing, moaning, and groaning are, as it were, sentences in a monosyllabic cosmopolitan language. These sounds are really the vocal representation of certain overwrought physical or mental states consequent in general upon a longer or shorter period of inhibition of the rhythmic discharge of the respiratory centre situated in the spinal bulb; the diaphragm has been fixed, the breath either voluntarily or involuntarily has been held or has been shallow whilst breathless introspective attention has been paid to some absorbing pain or sorrow. This condition is markedly present in patients suffering from melancholia who continually and deeply sigh. If this expression of excessive psychical

stimulation is rapidly and vigorously performed a cry of anguish or of fright may result, whereas at the other end of this series of phenomena is the feeling of "wanting to sigh," well known among those who are run down in general health. At times these sounds are emitted with the sole object of eliciting the sympathy of bystanders; this is notably the case with hysterical cries. There is, however, no doubt that there are considerable mental comfort and relief obtained from a series of long-drawn sighs during a period of sorrowful depression or from noisy ejaculations of the nature of groans and moans made by a sufferer from such a painful disorder as acute dyspepsia or violent toothache.

THE RIGHT HONOURABLE SIR WALTER FOSTER, P.C.

THE granting to Sir B. Walter Foster of the dignity of a Privy Councillor is a well-merited distinction to a member of the medical profession, although the honour, so rarely gained by medical men, has in his case been awarded almost wholly for political work. From 1892 to 1895 Sir Walter Foster acted as Parliamentary Secretary to the Local Government Board, having as Member of Parliament for the Ilkeston division of Derbyshire faithfully served his constituency and party. At the Local Government Board he was recognised by both sides of the House as a thoroughly able and conscientious administrator, and the medical profession, who perforce regard the Board as the medical bureau of the country, felt safe in his hands. Sir Walter Foster has contributed to the literature of medicine both from the point of view of the treatment of disease and in the wider aspect of public health, has been an important and energetic member of the British Medical Association, and was for ten years a Direct Representative of the medical profession upon the General Medical Council.

THE EVOLUTION OF THE TREATMENT OF SEROUS PLEURISY.

THE history of the treatment of serous pleurisy is an interesting one. As Dr. William Ewart remarked at a recent meeting of the Chelsea Clinical Society, little progress was made until the beginning of the nineteenth century. Dr. Ewart thought that the cause of this long delay was clearly traceable to the absence of clinical methods of diagnosis until Laennec's discovery of auscultation. The recognition that certain symptoms were produced by the collection of fluid in the pleural sac naturally led physicians to seek for some methods by which the effusion could be removed. Dr. Ewart's remarks in this connexion were valuable. He pointed out that three periods might be distinguished in the evolution of treatment: (1) from 1800 to 1834 therapeutic measures were purely medical—paracentesis was hardly ever practised; (2) from 1834 to 1869 (from Davies to Dieulafoy) paracentesis gradually came into fashion—this was a mixed period, partly medical and partly surgical; and (3) from 1869 onwards the treatment became almost exclusively surgical and medication fell into the background. Dr. Ewart then mentioned the principal steps in improved surgical procedure which had from time to time been introduced—the exploratory puncture employed by Davies (1834); the use of the syphon suggested by Carter in 1830 and ultimately elaborated by Potain and by Sir Richard Douglas Powell; and the construction of the aspirator by Stamsky in 1841 and its subsequent improvement by Dieulafoy in 1869 and by Potain in 1872. The methods employed at the present time differ, some practitioners preferring the syphon and others the aspirator, but in the majority of cases the use of the exploring needle precedes actual withdrawal of the fluid. In considering the medical therapeutics of serous pleurisy Dr. Ewart remarked that the English school took the lead

¹ THE LANCET: Yawning, Jan. 21st, 1905, p. 173; Hiccough, August 25th, 1905, p. 616.

in advocating the common-sense principle of feeding instead of starving the sick. He was further of opinion that the "expectant treatment," derived from the scepticism of science on the one hand and of Hahnemann on the other, rapidly gained ground and paved the way for a growing neglect of drug treatment. More recently certain measures have been suggested having for their object the prevention of the re-accumulation of the fluid. In referring to this part of the subject Dr. Ewart mentioned the method published by Sir James Barr, which includes not only the injection of air but the after-injection of adrenalin, and which may therefore be regarded as a "combined medico-surgical" method. This combination was also stated to be a feature in the "preliminary treatment" of serous pleurisy. Dr. Ewart maintained that much might be effected medicinally by way of preparation before paracentesis to insure successful re-absorption of the remnants of the effusion. He stated that the "preliminary intravenous injection method" provided in addition a local preparatory treatment of the pleura. Hitherto adrenalin had been used, as in Sir James Barr's method, but other agents might become available. Dr. Ewart went even a step further and related a case in which the preliminary injection led to re-absorption and so obviated the necessity of tapping. He hoped, therefore, that in a proportion of cases the preliminary injection might in itself be a method of cure. The recurrence of effusion after paracentesis is by no means an uncommon event and any measure by which this may be prevented is well worthy of trial. The remarks made by Dr. Ewart merit attention, for they deal with a condition which is constantly met with in the ordinary course of practice.

MEDICAL RECIPROCITY WITH JAPAN.

At the last session of the General Medical Council the motion of Dr. Norman Moore that the second part of the Medical Act, 1886, should apply to the empire of Japan was carried without discussion. The recommendation of the Council was approved at a meeting of the Privy Council in December last and has now been duly recorded in the columns of the *London Gazette*. This will subsequently give to Japanese medical men the right to be registered as foreign practitioners in the Medical Register. This recognition of the excellence of the medical work done by our Japanese allies will be approved by all British medical men.

WE understand that arrangements are being made for erecting a memorial to Dr. Ernst Ziegler, professor of pathological anatomy in the University of Freiburg in Baden, who died on Nov. 30th last. As already mentioned in THE LANCET of Dec. 23rd, 1905, p. 1874, Professor Ziegler was a well-known authority on pathological subjects and the founder of two periodicals. He was also highly esteemed as a teacher of pathology. Some new buildings, including a large lecture-room, are being constructed at the University and the present intention is to place a bust of the deceased in the lecture-room. Subscriptions are invited for this purpose and should be forwarded with the designation "Ziegler Ehrung" to Dr. Edgar Gierke, Freiburg i.-B., Rosastrasse 9.

Lord Rothschild, G.O.V.O., P.O., has accepted the office of President of, and Sir Frederick Treves, Bart., G.O.V.O., O.B., LL.D., the office of consulting surgeon to, the Royal Dental Hospital of London.

THE honour of a Privy Councillorship has been conferred upon Mr. Henry Labouchere, whose fearless exposures of fraud in the columns of *Truth* have earned the gratitude of medical men. His denunciations of numerous impostors

masquerading as healers of disease and thriving upon the credulity of the public have greatly helped our endeavours to curtail the rampant mischief of quackery. We congratulate Mr. Labouchere upon the honour that has been conferred upon him.

THE medical officer of health of the Cape Colony states that for the week ending Dec. 9th, 1905, the condition of the Colony as regards plague was as follows. No case of plague in man or other animal was discovered at any place throughout the Colony except at Port Elizabeth, where 1 plague-infected mouse was found. As regards the Mauritius a telegram from the Governor received at the Colonial Office on Dec. 29th states that for the week ending Dec. 28th there were 2 cases of plague and 2 deaths from the disease.

WE are requested to announce that the endowment fund now being raised for the family of the late Professor G. B. Howes, F.R.S., will shortly be closed and all intending contributors are asked to send their contributions without delay to the treasurer, Mr. Frank Crisp, at 17, Throgmorton-avenue, London, E.C.

Looking Back.

FROM

THE LANCET, SATURDAY, Jan. 5th, 1828.

A Correspondent who signs himself X.Y.Z., complains of the five years apprenticeship exacted by the regulations of the Apothecaries Company, and suggests an improved system of education in toto. As long as the profession remains under the ban of its present rulers, no remedy can be effective; nothing short of a radical extinction of the present accursed system will avail, and that this will speedily occur, our correspondent may rest assured. The latter observations apply to the letter of Mr. ALISON, of East Retford, who complains that medical men have not the power of legally enforcing payment for attendance, and cites the authority of an eminent counsel to that effect. All this, we repeat, is to be traced to the imbecility and sapineness of our rulers, or rather, to the wretched and narrow-minded policy which dictated the framing of laws for their own immediate benefit, whilst the majority of the profession remain unprotected.

The Worshipful Company of Apothecaries seem to be universally despised; we have literally a pile of letters from various sources, complaining of their "worships." One signed W.P. speaks of the injustice resulting from the inquisitorial power possessed by this Drug Company, of visiting the shops of apothecaries and inspecting the drugs—destroying them too, if in the plenitude of their wisdom they should deem fit. It certainly is a most odious enactment—one that is in direct violation of every principle of justice, and utterly opposed to the boasted liberty of the subject. *Prima facie*, the thing is glaringly absurd, that vendors of drugs should be made the judges of articles, furnished by rival traders.

With respect to the late regulations of the Company, on which subject we have many letters, we have already expressed our opinions. Well, indeed, might Napoleon exclaim, that the English were but a nation of shopkeepers, when we reflect, that the sacred trust of regulating and superintending medical education, is here placed in the hands of an ignorant herd of drug dealers.

An Occasional Contributor laments the want of means in our public charities, for giving to the sick the advantages of locomotion in the open air, so essentially beneficial in many diseases.

The *Per-centage* system alluded to by our correspondent, F.P., from Cheltenham, as existing between a certain physician and druggist of that town, is truly disgraceful.

¹ Excerpts from "a compendium—a digest of the mass of correspondence now lying before us" entitled "Excerpta quadam ex Epistolis Amicorum."

THE ADULTERATION OF SILK WITH TIN AND OF FLANNEL WITH EPSOM SALTS.

So long ago as 1899 this subject received attention in our columns when the results of a detailed examination, carried out in THE LANCET Laboratory, of a large number of dress materials were published.¹ Analysis showed that what in wearing apparel may fairly be regarded as foreign matter was frequently present in considerable quantity and it was pointed out that many of these mineral substances, although apparently insoluble under ordinary conditions, were in most cases rendered soluble by the action of perspiration. Consequently, there was risk that poisonous substances might be brought into intimate contact with the skin under conditions favourable to their absorption. Although only insignificant traces of arsenic were discovered, zinc, aluminium, chromium, tin, magnesium, and iron were found, and, calculated upon the total weight of material sufficient to form a dress, it was found that the mineral matter present varied from one-tenth of an ounce to as much as nearly six ounces. Recent experiments made in THE LANCET Laboratory upon a number of samples of silk bought in the ordinary way at West-end drapery establishments would seem to show that the evil in question has certainly not diminished since the former article on the subject appeared; in fact, recent inquiries indicate that the loading and adulteration of fabrics have during the last few years become a very serious question for the community.

The adulterant found in the samples of silk recently examined is stannic salt and the quantity present in one case was nearly 36 per cent. The following is a list of some of the actual amounts discovered, from which it will be seen that although there was considerable variation in the quantities of tin present none of the samples examined was guiltless of the adulterant.

Analyses of Six Pieces of Silk.

Piece.	Percentage of total mineral matter.	Percentage of tin calculated as stannic oxide (SnO ₂).	Percentage of real silk present.*
1	34.00	29.00	57.36
2	34.30	29.80	55.70
3	24.20	19.50	60.00
4	42.40	31.60	60.00
5	42.40	31.60	50.00
6	47.10	35.90	50.00
Averages...	37.40	29.60	53.84

* The percentage of real silk present is calculated from the amount of nitrogen present, 18 per cent. of which represents 100 per cent. of silk. The nitrogen therefore multiplied by 5.5 gives the real silk present.

The adulteration of silk has now become such an established "industry" that a short statement of the process by which it is effected may prove interesting. One of the principal substances composing raw silk and one which may be considered as the active substance in the silk is known as sericine. This has a slightly acid reaction and a power of combining directly with metallic oxides and basic dyes and advantage is taken of this fact to weight cheap silks to an enormous extent with tin. The method of procedure is to soak the silk for several hours in a solution of stannic chloride, after which the fabric is passed through a cold solution of carbonate of soda to set free the tin in a basic condition, so that it can combine with the sericine. A bath in neutral soap solution to make the fibre supple and to increase its affinity for more weighting material follows and the fabric is now ready to take another turn in the tin bath. Three passages through this process will increase the weight of the silk by from 25 per cent. to 30 per cent., six by 50 per cent., seven by 75 per cent., eight by from 90 per cent. to 100 per cent., and ten by about 160 per cent. The weighting process is carried out in darkened rooms, as sunlight or any

strong light renders the silk brittle during these operations. Although the strength of the fibre is greatly reduced the appearance and lustre of the silk do not seem to be affected seriously for the time being. All goes well so long as the fabric is kept in the dark, but as soon as it is worn the light decomposes the compound of the tin and the sericine, producing oxide of tin and free acids, which rapidly destroy what is left of the fibre, so that a garment of weighted silk will tear in the wash under ordinary handling, especially under the armpits where the effect of perspiration has been added to the other destructive agencies. As this cheap silk is used not only for dress-making *per se* but as lining for other dress materials, it frequently comes in contact with the skin, and even in cases where underclothing may protect the skin from immediate contact with the silk there is always the risk that perspiration may set free the oxide of tin in a soluble form and by its absorption by the other materials bring it in direct contact with the skin, so that the wearer of such material runs considerable danger of local irritation being set up, if nothing worse.

Before passing on to other materials we must call attention to a particularly obnoxious method which is in use for colouring, we cannot call it dyeing, the cheap materials used for linings and similar purposes. In this case the dye is made up into a kind of paste with some sizing material and instead of the fabric being properly dyed this coloured size is spread over the surface by rollers. When dry it has a perfect appearance and the fraud is not distinguished until the fabric is brought in contact with moisture, either in the wash or through perspiration, when the dye practically leaves the fabric. Although it is true that the majority of the dyes derived from aniline and what are known generally as coal-tar colours are very much faster to light than they used to be, the lack of fastness to soap and water, which many of the materials at present in use exhibit, is a source of serious complaint from laundrymen and those who have to handle them. A suit of flannelette pyjamas, upon which we recently made some experiments, was of a very pleasant blue shade when purchased but in two washings the colour was completely removed. Instances of this kind might be multiplied almost indefinitely from other instances which have come under our own experience or have been brought to our notice by laundrymen from whom we have made inquiries.

The loading of fabrics intended for wearing apparel is by no means confined to silk and is such a serious factor in the manufacture of the cheaper varieties of flannel, amongst which we may include blankets, that in sorting the various articles which come into the laundry before going through the cleansing process a laundryman has to be very careful to pick out any new goods of this description and to wash them separately, otherwise the large amount of loading material which they contain might interfere so seriously with the washing process as to necessitate a second washing of a whole batch of goods. This is even more true of the cotton bands, &c., attached to the woollen materials, which usually receive separate treatment. This weighting of material is so serious in almost every department that it is quite a revelation to see the quantity of loading material, largely china clay, which is washed out of cheap table linen and similar goods and to observe what a very little of the apparently stout fabric appears to be left after contact with water for a few minutes. We must recall also that in our previous investigation into the amount of mineral matter in dress fabrics we discovered considerable proportions of Epsom salts and zinc compounds in flannel.

It would be bad enough if the sophistication of fabrics were confined to loading them, but unfortunately this is not the case. The modern manufacturer in many instances adulterates the fibre of his fabric first and loads it afterwards. Silk is adulterated with artificial silk made from cellulose, flannel and woollen material with cotton, linen with cotton, whilst "mercerised" cotton is employed in many ways. Some of these mixtures of fibres are quite legitimate, but a good many are not, and amongst the most serious of which the community has to complain at the present time is the adulteration of linen with cotton. The substitution of cotton for linen has become so serious that the Irish flax spinners have been compelled to take action in self-defence and prosecutions of retailers have occurred in most of our principal towns. They form very interesting reading for they show that a certain section of the retail trade has become so lost to a sense of right and wrong that it is seriously claiming that

¹ THE LANCET, Oct. 25th, 1899, pp. 1155-57.

the passing-off of cotton goods for linen is a trade custom and therefore justifiable. The common practice seems to be to sell cotton shirts or collars or "fronts" made of one-ply linen and two-ply cotton, or in other proportion according to the nature of the garment. In many cases these were actually sold as "all linen" and so described on the invoice.

In a recent prosecution at Bradford the manager of a firm seriously contended that the word "linen" was the trade term for linen-fronted goods and that it did not necessarily imply that in their trade the goods so described were all flax. In reply to a question from the stipendiary magistrate the witness admitted that he had not a single all-linen collar in his place—not one that he would guarantee to be pure linen. A defendant at another court remarked that he did not believe that anyone present was wearing an all-linen collar; he felt quite sure that the prosecuting inspector's collar was cotton; and so on.

Now, whatever may be the hygienic difference between cotton and linen, there is a large difference in the cost and in the wearing capabilities. Cotton fabrics disintegrate comparatively readily, the fibre being much shorter than linen, whereas linen has a long and very strong fibre. The consequence is that cotton fabrics contribute rapidly to the formation of that fluff which is the bugbear of the modern housewife. The table-linen not so very long ago consisted wholly of linen; nowadays a large proportion of it consists of a cotton warp and a linen weft and sometimes it is entirely of cotton. In the wash the difference soon becomes apparent; an appreciable amount of fibre becomes separated from the surface of the cotton fabric, and although a certain amount is removed in the rinsings yet a large proportion remains clinging to the materials when dry. In use this soon becomes separated and adds appreciably to the dust and dirt of the living-room. In some of these loosely woven table cloths, which are sent out felted together with size, starch, and china clay, so that they look thick and solid, the fluff is so serious that if a laundryman happens by misfortune to wash one in a batch with other table linen it will contaminate the whole, and the unfortunate customer who uses good table linen is horrified to think that the laundryman is destroying her expensive fabrics in the most ruthless manner. The wholesale adulteration of linen has become so serious that a large linen shop in the West-end of London is, or was a short time since, placarded with notices to the effect that on account of the difficulty of distinguishing between cotton and linen the assistants were forbidden to give any kind of warranty. This notice is akin to the announcement by which many publicans evade the Sale of Food and Drugs Act—namely, by stating that spirits are sold as "diluted."

To take the case of flannels and woollens again: these are frequently adulterated with cotton and loaded, although in a different manner from cotton, but even amongst the numerous goods that are sold as natural wool and guaranteed unshrinkable many are found to which this term can only be applied in derision. On account of the construction of the fibre, woollen goods if not washed with great care are always liable to shrinkage, but unless they have been very badly treated this shrinkage should not be great if the fabric is properly shrunk in a soap liquor before the garments are made up. A large number of the garments now sold through the retail hosiers and linendrapers are not properly shrunk, even in the case of some which are largely advertised and are supposed to bear a high name for quality, the result being that the shrinkage is excessive. The wool fibre is covered with a number of serrations and these have a tendency to interlock and to pull the fabric closer and closer together, especially if during the washing process the fabric is subjected to serious changes of temperature, such as removing from hot water into cold, which causes the fibres to move. It has been discovered, however, that treatment of the fibre with hydrochloric acid will cause such an alteration in these barbed tips that the fibres have no longer a tendency to interlock, although they are not seriously affected in any other respect, and a large quantity of woollen underclothing which, to use the trade term, has been "kymed" is now on the market.

Shrinkage is not confined to woollen goods, as cotton goods will sometimes shrink along the warp when being washed for the first time. In the modern power loom the fibres are often severely stretched in the direction of the warp and the fabric takes the first opportunity of recovering itself when moistened. On the other hand, we have been shown some samples of chintz which have been causing a

veritable panic amongst the furnishing houses and dyers and cleaners. An ordinary width of this when wetted stretches two inches. The effect of this upon a suit of chintz furniture covering and the feelings of the housewife when she gets it home can readily be imagined.

Yet another very important difference between the old and the new style of fabric is in the length and strength of the fibres employed. The short staple wool, for instance, which is now largely woven into our garments, would have been discarded not many years ago and employed only for making felt, being regarded as too short to weave into satisfactory yarn. In cotton and linen, again, especially the latter, there is nothing like the care employed in selecting the fibres that there used to be, with the consequence that they break much more frequently in the weaving, apart from possessing much less intrinsic strength. Here again there is no time to knot the broken ends properly together but they are given a twist which secures them for the time being. As soon as the size is washed out of the goods when they go to the laundry many of these broken ends develop into holes and we have had a large number of tablecloths submitted to us for examination in which these holes could be traced in various stages of progress. Examination with an ordinary magnifying glass was quite sufficient to show what was wrong with the fabric. Bleaching, again, is conducted in a hurry and the methods employed are much more drastic than they used to be, with the natural result of a seriously weakened fibre.

From the instances which we have given above it will be seen that the trade in fabrics is in as bad a condition now as regards adulteration as was the trade in food and drugs when THE LANCET first stepped into the arena in 1890 to combat the demon of adulteration, and the question arises, What remedies can we propose? The only weapon that the public at present possesses is the Merchandise Marks Act, which penalises a trader for applying a false description to his goods. As applied to the drapery and hosiery trade, however, and regarded from the ordinary purchaser's point of view, this Act suffers from the defect that not only can a coach-and-four be driven through it but two motor-cars as well. Except where cotton is wrongly described as linen it is practically impossible to apply the Act to cases of deception in the sale of fabrics. The trader is much too wily to be caught in such a very loosely woven net as the Merchandise Marks Act. He simply applies some adjective to the word describing the material—he calls it "Chinese silk," "Cathay silk," "Carthaginian silk," anything but "silk"—and is safe. Similarly with flannel, it rarely appears in the linen-draper's window without some patriotic adjective—it is Welsh flannel, Scotch flannel, Irish flannel, but very rarely flannel; certainly not "pure flannel." However desirable it might be in theory to compel manufacturers and retailers to apply correct descriptions to their goods, it would hardly be practicable to compel them to placard their windows with such announcements as "Tin silks: all the rage," "Epsom-salted flannels," "China clay table linen," and so forth, however accurate such descriptions might be. It is equally impracticable to expect customers to demand a warranty with every yard of material which they buy, because, in the first place, they would not ask for it and in the second place they would not get the warranty if they did. Not long since we asked for a written guarantee at a certain wool-shop that the underclothing which we were about to purchase, although warranted in the firm's advertisements not to shrink, would not do so in reality but were refused on the ground that the firm did not know what laundry we were going to send it to. And this brings us to another very serious matter—namely, that the sophisticators of fabrics—manufacturers, wholesalers, and retailers together—are endeavouring to pass the responsibility for their misdeeds on to the unfortunate laundryman or dyer and cleaner who, in nine cases out of ten, is in no way to blame. The bad-wearing qualities of the table linen, which goes into holes on the first wash, the raw edges on the collars, the thinness of the blankets, and so forth, are attributed to the laundryman's chemicals and machinery, instead of to the fraudulent methods employed in the manufacture and sale of the goods. Ladies compare the wearing qualities of the linen that their mothers used to buy with that which they purchase themselves and put the blame on the laundries for the bad qualities of the latter. Good linen, for example, will wear well even in the modern laundry and in proof of this we were shown a handkerchief

not long ago which had gone regularly through the wash for almost a generation, including many years' washing in a modern steam laundry, and which appeared to be little the worse. Such things can hardly be bought nowadays, even if a purchaser is willing to pay a high price. To take the case of the faded silk again, which we have recently analysed: the silk blouse which appeared so charming when new crumbles almost at once in the sun, the tin is converted into oxide, which is removed as powder in the wash, the acid attacks the fibre and causes it to go into holes as soon as it reaches the hands of the laundryman or dyer and cleaner, and when its once proud possessor receives back the rag which was once a blouse, her wrath is expended not upon the draper who sold it but upon the unfortunate dyer and cleaner to whom was intrusted the impossible task of rendering it equal to new.

In distributing the blame we must not place the whole of it upon the shoulders of the manufacturers and retailers, bad as they are, but must mete out a considerable share to the fair sex who in their desire to obtain showy materials at a cheap rate give direct encouragement to these objectionable practices. Every year the cry goes forth for something cheaper than last year that will look as well and the draper is only too ready to meet the demand and to encourage it. Nevertheless, it must be borne in mind that the sophistications are so skilfully conducted that they would deceive all but the expert, and the housewife with a limited purse can hardly be severely blamed if she buys at cheap prices goods which look all right. The real and most serious blame must be laid at the door of the manufacturer and retailer and the only way that we can see open at the moment to save the unfortunate customer from their devices is to educate her as rapidly as possible concerning the practices which are in vogue. This is certainly a large undertaking but so far as we can see it is the only way to grapple with the difficulty in the absence of some drastic legislative measure. One practice that we should certainly like to see prohibited at the earliest moment is the loading of fabrics of any kind with mineral matter—we do not include the mordants which may be necessary to fix the dyes on the material. This practice of loading goods with china clay and other materials was designed in the first instance to swindle the unsuspecting Hindoo who buys his cotton cloth by weight instead of by length and the practice has now spread to the greater part of the goods on the home market. Such loading, whether it be carried out in cotton, linen, or silk, serves no good purpose whatever; it is simply a fraud and is quite unjustifiable. Moreover, we are still of the opinion stated in our previous article that in addition to the actual danger to health caused by the presence of the irritant mineral poisons in dress fabrics, the presence of mineral substances generally "tends to nullify the important properties of clothing of keeping the body warm and protecting it from the cold and, above all, of allowing the free passage of air from within and without."

CHOLERA AND PLAGUE IN RUSSIA.

(FROM THE BRITISH DELEGATE ON THE CONSTANTINOPLE BOARD OF HEALTH.)

THE following returns of cholera cases and deaths in the Polish governments of Russia are in continuation of those furnished in my last letter (THE LANCET, Dec. 9th, p. 1730).

From Oct. 6th (19th) to 13th (26th):—

In the government of Lomza	5 cases	2 deaths.
" " Piotrkow	5 "	0 "
" " Warsaw	2 "	1 death.
" " Plock	1 case	1 "

From Oct. 14th (27th) to Oct. 19th (Nov. 1st):—

In the government of Lomza	5 cases	1 death.
" " Warsaw	1 case	0 deaths.
" " Piotrkow	7 cases	0 "
	and 5 suspected cases.	

From Oct. 19th (Nov. 1st) to Oct. 22nd (Nov. 4th):—

In the government of Lomza	1 case	0 deaths.
" " Lodz	6 suspected cases.	
" " Warsaw	3 "	

From Oct. 24th to 25th (Nov. 6th to 7th) there were 12 cases and 12 deaths in the Polish governments and one

suspected case. On the 26th (Nov. 8th) three deaths occurred; from Oct. 27th (Nov. 9th) to Nov. 2nd (15th) there were 18 cases and nine deaths in the Lomza government; and between the 7th (20th) and the 8th (21st) there were 11 cases and two deaths in the same government. Finally, between Nov. 10th (23rd) and Nov. 30th (Dec. 13th) 24 cases and seven deaths were recorded in the Lomza government.

An outbreak of plague of considerable severity is reported from the Kirghiz steppes of the government of Astrakhan. The disease appeared among a number of Kirghiz settlements in the Naryn district, 250 versts (about 160 miles) from the Khanskaia Stavka. Between Oct. 13th (26th) and Nov. 2nd (15th), in ten settlements extending over an area of 50 versts, as many as 40 "zemlianki" (earth huts) became infected; and 58 persons were attacked by the disease, of whom 23 died. On Nov. 1st (14th) a suspected case occurred in the territory of the Koundrov Tartars in a person arriving from the Naryn district. A second report states that the number of infected "zemlianki" had risen to 71, of which 59 are in the Naryn district and 12 in the First and Second Primorskoi (or Maritime) districts. In the Naryn district 80 deaths had occurred from the disease up to Nov. 8th (21st) and in the two maritime districts 18 deaths had been recorded to the same date. Plague had also appeared in the settlement of Djandakul, in the district of Krasnoyarsk, where 14 deaths had been reported up to Nov. 9th (22nd).

The latest report received here states that between Nov. 12th (25th) and 17th (30th) there had been 33 cases of plague and 41 deaths in the Naryn district, three cases and five deaths in the first, and six cases with 16 deaths in the second maritime district. In the Taigoul community, in the Krasnoyarsk district, six cases and six deaths had been observed. The total number of cases in the Kirghiz steppe had been 293 and of deaths 279, while in the Krasnoyarsk district the cases numbered 23 and the deaths also 23. No further information has been received of the outbreak of plague on the Siberia-Manchurian frontier mentioned in my last letter.

Constantinople, Dec. 23rd, 1905.

REQUESTS TO HOSPITALS IN THE BIRMINGHAM DISTRICT.—The late Mr. John Feeney, one of the proprietors of the *Birmingham Daily Post*, has bequeathed by his will sums amounting to £89,000 to various institutions connected with Birmingham and the district. These include the Birmingham Art Gallery, £50,000; the University of Birmingham, £20,000; the General Hospital, £10,000; and £1000 each to the Queen's Hospital, the General Dispensary, the Eye Hospital, the Women's Hospital, the Children's Hospital, the Blind Asylum, the Middlemore Emigration Homes, the Wolverhampton Infirmary, and the Coventry Hospital. All the above bequests are given free of legacy duty but payment cannot be claimed until the expiration of five years. The bequest to the University is for the purpose of maintaining a professor, with suitable equipment, lecturing on some one or more scientific subjects directly connected with some one or more of the trades and industries carried on in or near Birmingham. This bequest makes a total of £80,000 which the University has received within a period of little more than a month. Under the will of the late Mrs. Hannah Finnie of Malvern Wells £3000 are bequeathed to the Midland Counties' Home for Incurables. The Worcester Infirmary has lately benefited by the following legacies: £200 from Mr. Charles Taylor of Holloway, London, and £100 from Mr. George Arden of Towyn.

LITIGATION REGARDING THE VALUE OF A PRACTICE.—The case of *Coumbe v. Davies* was heard on Dec. 18th, 1905, in the King's Bench Division before Mr. Justice Channell. In this action Dr. J. B. Coumbe sued Mr. G. A. Davies for damages for losses caused by the alleged misrepresentation of the defendant in regard to the value of a medical practice which the plaintiff purchased from the defendant in Newport (Mon.) for £1600. The defendant said that the representations made were true and that the plaintiff was fully aware of all the facts when he bought the practice. The judge stated it would be necessary for Dr. Coumbe to call evidence in support of his charge of fraudulent misrepresentation. Mr. Shee, K.C., said that after the remarks of the judge he proposed not to persist in the charges and they would be withdrawn. Judgment was entered for the defendant with costs.

THE LANCET RELIEF FUND.

THIS Fund, which came into operation on the 1st of February, 1889, has for its Almoners the President of the Royal College of Physicians of London (Sir RICHARD DOUGLAS POWELL, Bart., K.C.V.O., M.D. Lond.), the President of the Royal College of Surgeons of England (Mr. JOHN TWEEDY), the President of the General Medical Council (Dr. DONALD MACALISTER, M.A., B.Sc., F.R.C.P. Lond.), Mr. THOMAS WAKLEY, F.R.C.S. Eng., and Mr. THOMAS WAKLEY, jun., L.R.C.P. Lond., with Sir HENRY PITMAN, M.D. Cantab., F.R.C.P. Lond., as Honorary Auditor.

FOR the guidance of those seeking assistance and of those desirous of recommending deserving cases, it may be useful to record that THE LANCET Relief Fund is sustained solely by the Proprietors of THE LANCET, who provide every January the sum of at least £300, which is administered free of cost, with the object of affording immediate pecuniary assistance to registered medical practitioners, or to their widows and orphans, in cases of distress and emergency, by the grant of money by way of loans free of interest, or gifts, as the circumstances of the various cases may require. In the case of widows and orphans, in order to come within the scope of the Fund, the death of the Husband or Father must have been of recent occurrence.

WHEN the Fund was inaugurated considerable misapprehension existed as to the precise objects for which it had been established, and, as a result, the majority of the earlier applications, being cases of *chronic* distress, and not coming, therefore, under the designation of *emergency*, could not be entertained. As the Almoners still receive applications for assistance for cases which are obviously of a *chronic* character, it is thought advisable to append a statement concerning cases of this nature which appeared in THE LANCET of Feb. 16th, 1889:—

"We are requested by the Almoners to state that, from the character of a number of the applications received, both personally and by letter, for relief, it is evident that in many cases the object for which this Fund has been established is not quite clearly understood; and if relief had been afforded in the cases of those who suffer from chronic distress the Fund would have been completely exhausted within the first few days of its existence. They would therefore be greatly obliged if those readers of THE LANCET who may be asked to endorse applications would carefully peruse the Application Form and explain the precise object of the Fund to those applicants whose cases do not seem to come within the scope of the purpose for which the Fund has been established, which is to afford prompt aid to registered medical practitioners, or to the widows or orphans of members of the profession, who, in consequence of the supervision of some unexpected emergency, which is not likely to recur, have pressing need of immediate and temporary pecuniary relief"—

And who, it may be again pointed out, are likely to be benefited permanently thereby.

Seventeenth Annual Report of the Almoners, For the year ending December 31, 1905.

In presenting their Seventeenth Annual Report the Almoners have to record that the balance in hand on Dec. 31st, 1904, was £225 2s. 3d., to which, on Jan. 1st, 1905, the Proprietors of THE LANCET added the sum of £300, making a total sum of £525 2s. 3d. available for grants during the year 1905.

The number of applications received by the Almoners during the year for assistance was 61, of which number nine were rejected by the Secretary as quite outside the scope of the Fund; seven were declined by the Almoners after due consideration; two applications were received on behalf of one person; 12 Application Forms failed to be returned—doubtless owing to the applicants realising that their cases were not of the nature qualified to receive assistance from the Fund; and 32 applicants were relieved by gifts or loans ranging from £5 to £25. The relief of these 32 cases, a detailed list of which is given in the accompanying Statement of Accounts, involved the expenditure of the sum of £313—an amount just above the normal income of the year. One of the cases relieved came from Australia. The balance at the bank on Dec. 31st, 1905, was £232 13s. 1d.

Many expressions of gratitude for the assistance afforded to applicants have been received by the Almoners; and it is a pleasure to record that in several instances the timely help that the Almoners have been able to give has been the means of averting consequences which could not fail to be disastrous to the applicants had their appeals not met with a ready response. In this connexion it may be mentioned that one case brought to the notice of the Almoners threatened the breaking up of a practice, and the ruin of the practitioner who had worked hard to keep it together during a period of depression, unless a sufficient sum were forthcoming to pay off pressing domestic creditors. Within three hours of the application being received the Almoners had considered the case, doubled the amount of help asked for, and saved the applicant and his family from having the means of their livelihood taken away from them. Several other instances of equally prompt relief might be cited; but they are referred to only in order to emphasise what is to the Almoners a pleasing feature of the Fund which they are called upon to administer—*immediate relief in urgent cases*.
Of applications of a "chronic" character there are still far

too many. A large number have again been rejected, and in some cases the inability of the Almoners to assist has produced anything but complimentary replies. It is quite obvious that the assistance which the Almoners could give would mean only a few days' or weeks' temporary respite to cases of this character—no permanent good could possibly be effected; and it cannot be too emphatically reiterated that THE LANCET Relief Fund exists to meet cases of *sudden emergency*, where timely help will tide the practitioner over unforeseen difficulties, or will afford his widow and orphans temporary relief at the moment of their greatest trial.

Sir Richard Douglas Powell, Bart., K.C.V.O., M.D. Lond., having succeeded Sir William Church, Bart., K.C.B., M.D. Oxon., as President of the Royal College of Physicians of London in April last, thereupon became an Almoner of the Fund, and kindly consented to act as such. The Almoners at their last Annual Meeting had pleasure in causing to be

recorded on the Minutes their warm appreciation of the valuable services rendered to the Fund by Sir William Church throughout the six years during which he acted as one of the Almoners.

In conclusion, the Almoners desire to state that they will at all times be glad to have their attention called to any cases of genuine distress coming within the scope of the Fund but they trust that those recommending cases or giving testimonials will first take steps to satisfy themselves of the *bona fides* of such cases before endorsing them. In the administration of such a Fund as this the Almoners are of necessity largely guided in their decisions by the testimonials accompanying the applications.

I find by the Bankers' Book that the actual Balance on Jan. 1st, 1905, to the credit of the Fund was £225 2s. 3d., to which the sum of £300 was added by the Proprietors of THE LANCET on Jan. 1st, 1905. The balance at the Bank on Dec. 31st, 1905, was the sum of £232 13s. 1d. I have also checked the receipts for disbursements and find the above account strictly accurate.

January 1st, 1906,

HENRY A. PITMAN, Hon. Auditor.

MEDICINE AND THE LAW.

The Fees of Medical Witnesses at Inquests.

AT Lydd recently at an inquest upon the body of a coast-guard a discussion took place between the coroner and a medical man which had as its result the refusal of the medical man to give evidence after the coroner had taken a view of the law which appears to us to be entirely wrong. The coastguard had met with an injury, for which he was attended by Mr. J. A. Procter of Lydd until he appeared to be nearly well. Mr. Procter, however, asked him to come to see him once more on a day named and the man walked some distance to the surgery in order to do so. Mr. Procter had meanwhile been called away to attend a case elsewhere and had asked a medical friend, Mr. O. A. Gaitskell, to see the man in his absence. Mr. Gaitskell on going into the surgery after being informed that the patient was there found him lying on the ground with blood issuing from his nose and mouth and death took place before he could be removed. In these circumstances Mr. Procter was of opinion that the death was not the result of the accident mentioned above and refused to give a certificate to that effect. At the inquest (which, by the way, would have been rightly held in any case) he repeated this opinion and the jury very properly expressed a wish to hear what Mr. Gaitskell, who was with the deceased at the time of his death, might have to say. If they had also insisted on the necessity for a post-mortem examination in such circumstances they would have made an even more useful suggestion, but apparently none was ever held. Mr. Gaitskell arrived and asked before being sworn as a witness that his fee might be paid. In reply the coroner said that only one fee could be allowed to a medical witness and this, as one was already due to Mr. Procter in respect of the evidence which he had given, meant that Mr. Gaitskell would receive nothing. The coroner appears further to have expressed surprise at the question being raised and to have given vent to the observation that the medical man's conduct was ungentlemanly. Mr. Gaitskell upon this declined to give evidence and the only other statement of the coroner which merits comment is one reported in the *Kent County Examiner* to the effect that in 40 years' experience he had never had a similar case. As the coroner referred to so long an experience he may have explanations to give as to what occurred at this inquest which are not before us, but we may point out that the verdict which the jury delivered was, in the absence of post-mortem examination and in the teeth of the opinion expressed by Mr. Procter, arrived at practically by conjecture on their part and not founded upon evidence. They found that the coastguard died "from internal hæmorrhage caused by injuries received by the deceased by the overturning of a boat" and added a rider recommending that the medical officer should visit coastguards when ill instead of their going to him. They had not before them any evidence as to whether this contributed in any way to the death or even as to how or where the death took place, for of course the statement of Mr. Procter of what Mr. Gaitskell, and perhaps others, had no doubt perfectly accurately described to him was not evidence at all. With regard to the discussion between the coroner and Mr. Gaitskell as to the latter's fee, we are inclined to think that his better course would have been to have given evidence and then to have brought an action to recover the fee due to him as a medical witness if it was not paid. The Coroners Act, 1887, contains nothing whatever to indicate that only one medical witness may be called and paid by the coroner. On the contrary, it says (Section 21) that "where it appears to the coroner that the deceased was attended at his death or during his last illness by any legally qualified medical practitioner the coroner may summon such practitioner as a witness." That is to say, in other words, any medical practitioner who has attended the deceased in his last illness may be called to give evidence. By Section 22 "a legally qualified medical practitioner who has attended at a coroner's inquest" as provided by the section quoted "shall be entitled" to the prescribed remuneration. If anything so absurd as the calling of one medical man only were intended, when the truth might be better ascertained by calling two, some expression which would put this beyond doubt could easily have been used. In the statute, moreover, which this section superseded (6 & 7 Will. IV., c. 89, repealed by the Act of 1887), the direction with regard to a

post-mortem examination is that it is to be intrusted to "the medical witness or witnesses who may be summoned; to attend" at any inquest, so that if the Act of 1887 were to have introduced intentionally a new restriction of the medical evidence to one witness it would be retrogressive in its effect. It is not necessary to demonstrate that the usefulness of the coroner's inquest would be considerably curtailed if he could only call one medical witness in any case, considering that the subject of the inquiry is the cause of death, where death has been apparently violent or unnatural, or a "sudden death whereof the cause is unknown."

Medical Evidence at Inquests and the Coroner for Anglesey.

A second inquest calls this week for notice in our regular summary of medico-legal events. The *Liverpool Courier* recently contained a report of an inquiry conducted, upon lines which are fortunately unusual, by Mr. R. Jones Roberts, coroner for Anglesey. A maiden lady living alone was found at the foot of the stairs in her house groaning and unconscious. She was attended by two medical men and died a short time afterwards. It will perhaps surprise those who read of this to learn that at the inquest two witnesses only were called, a child aged 14 years and a woman, both of whom knew no more about the matter than that they saw the deceased on a certain day lying on the ground, for she lived alone. When a juror afterwards asked whether any medical evidence would be called, the coroner said that "they would be no better off if they had it," and further that "it was not usual to call medical evidence in such a case. It was not absolutely necessary for the jury to know the cause of death. It was sufficient for them to say what their opinion was." To this he added some observations relating to the medical profession of a disparaging character and ended by giving as his motive in acting as he did the desire to save the money of the county, for which he described himself as a trustee. The statement that it is not usual to call medical evidence in such a case may be traversed without further comment. With regard to the duty of the jury they have "to inquire" as jurors touching the death and to certify, so far as such particulars have been proved to them, who the deceased was and how, when, and where he came by his death, and they have to find "the particulars for the time being required to be registered concerning the death." The coroner has a discretion, it is true, as to what witnesses he may examine but he is also responsible to the Crown for the proper conduct of inquests, and it is his duty to call the best evidence available as to the cause of death and not to leave the jury to form an "opinion" founded upon conjecture. If through the deliberate omission of a coroner to call a material witness, whether medical or not, a failure to arrive at a correct verdict were to take place the coroner might find his responsibility brought home to him in a serious manner.

Quackery among East-end Aliens.

We have before us an advertisement appearing in the *Jewish Journal*, a newspaper printed in Yiddish and having a considerable circulation among the poorer classes of Jews living in the East-end, or, as passages in the advertisement speciously suggest, passing through it on their way to the United States. Our American cousins do not welcome the diseased foreigner as warmly as we do and consequently the advertiser promises "Ease for those who intend to emigrate to America." Beyond this there are features in the advertisement to which attention may well be called, although the fact of it being printed in a foreign language and addressed to foreigners points to difficulties in the enforcement of the law such as it is. The last line is printed in English and describes the advertiser as "Dr. Leibovitz, 60, Mile End-road." Addressed to an English audience the use of the title "Dr." would certainly be dangerous for the gentleman named unless his qualifications were of a nature to justify it. The Yiddish part of his advertisement claims for him diplomas from New York and registration in the 31st District of Columbia. It also contains an allusion to the preparation of medicines "in his laboratory under the supervision of a qualified doctor." To what extent our translation may justify the suggestion that this would furnish a case for inquiry is a matter for the consideration of those concerned in protecting the poor from deception by persons of this class who advertise as this man does, that he will send his "new book on venereal diseases" to the residence of any who may send 3d. in stamps in payment and that he is ready to "perform operations without a knife and without any hæmorrhage."

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In 76 of the largest English towns 6415 births and 5197 deaths were registered during the week ending Dec. 30th, 1905. The annual rate of mortality in these towns, which had been 16.1, 17.0, and 17.8 per 1000 in the three preceding weeks, declined again to 17.4 per 1000 last week. In London the death-rate was 17.8 per 1000, while it averaged 17.2 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 7.5 in King's Norton, 8.1 in Hornsey, 10.1 in York, 10.7 in Reading and in Walsall, 11.7 in Wallasey, and 11.9 in Burton-on-Trent; the highest rates were 21.5 in Burnley, 22.3 in Newcastle-on-Tyne, 22.4 in Tynemouth, 24.2 in Huddersfield, 24.8 in Preston, 24.9 in Liverpool, 25.4 in Merthyr Tydfil, and 30.6 in Hanley. The 5197 deaths in these towns last week included 404 which were referred to the principal infectious diseases, against 373, 391, and 439 in the three preceding weeks; of these, 404 deaths, 117 resulted from measles, 91 from whooping-cough, 69 from diphtheria, 56 from diarrhoea, 43 from scarlet fever, and 28 from "fever" (principally enteric), but not any from small-pox. No death from any of these diseases was registered last week in Southampton, Northampton, Great Yarmouth, Devonport, Burton-on-Trent, Walsall, King's Norton, Bootle, Warrington, York, or Stockton-on-Tees; while the highest death-rates from the principal infectious diseases were recorded in Coventry, Stockport, Burnley, Blackburn, Preston, Leeds, Middlesbrough, Newcastle-on-Tyne, and Merthyr Tydfil. The greatest proportional mortality from measles occurred in Blackburn, Preston, and Leeds; from diphtheria in Middlesbrough and West Hartlepool; from whooping-cough in Rochdale, Burnley, and Newcastle-on-Tyne; from "fever" in Stockport and Wigan; and from diarrhoea in Coventry, Oldham, and Middlesbrough. The mortality from scarlet fever showed no marked excess in any of the large towns. No death from small-pox was registered last week in any of the large towns and no cases of this disease were under treatment during the week in the Metropolitan Asylums Hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had been 3888, 3670, and 3409 at the end of the three preceding weeks, had risen again to 3446 at the end of last week; 295 new cases were admitted during the week, against 355, 341, and 295 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 376, 460, and 516 in the three preceding weeks, declined again last week to 426 and were 95 below the number in the corresponding period of last year. The causes of 79, or 1.5 per cent., of the deaths in the 76 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Portsmouth, Nottingham, Salford, Bradford, Leeds, Newcastle-on-Tyne, and in 41 other smaller towns; the largest proportions of uncertified deaths were registered in Ipswich, Handsworth (Staffs.), Birmingham, Liverpool, Bootle, St. Helens, Manchester, Sheffield, Sunderland, South Shields, Gateshead, and Rhondda.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 19.9, 18.2, and 17.4 per 1000 in the three preceding weeks, rose again to 18.2 per 1000 during the week ending Dec. 30th, and was 1.8 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 15.2 in Paisley and 15.4 in Leith to 19.3 in Aberdeen and in Greenock and 22.9 in Dundee. The 609 deaths in these towns last week included 25 which were referred to measles, 14 to diarrhoea, 12 to diphtheria, seven to whooping-cough, four to "fever," and three to scarlet fever. In all 65 deaths resulted from these principal infectious diseases last week, against 77, 64, and 83 in the three preceding weeks. These 65 deaths were equal to an annual rate of 1.9 per 1000, which was 0.6 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of measles, which had been 45, 31, and 43 in the three preceding weeks, declined again last week to 25, of which 15 occurred in Glasgow, six in Dundee, and three in Greenock. The

deaths from diarrhoea, which had been 11, 18, and 15 in the three preceding weeks, further declined to 14 last week, and included five in Glasgow, three in Edinburgh, and three in Dundee. The fatal cases of diphtheria, which had been five, three, and 11 in the three preceding weeks, further rose last week to 12, of which five were registered in Glasgow, two in Dundee, and two in Greenock. The deaths from whooping-cough, which had been eight, six, and nine in the three preceding weeks, declined again to seven last week, and included three in Glasgow and two in Dundee. The fatal cases of "fever," which had been one, two, and four in the three preceding weeks, were again four last week, and included two in Glasgow, and two in Paisley. The deaths referred to diseases of the respiratory organs in these towns, which had been 126, 117, and 130 in the three preceding weeks, declined again last week to 99 and were 85 below the number in the corresponding period of last year. The causes of 18, or nearly 3 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 22.0, 19.7, and 22.3 per 1000 in the three preceding weeks, declined again to 17.9 per 1000 during the week ending Dec. 30th. During the 13 weeks of the quarter ending on that date the death-rate averaged 20.4 per 1000, the rates during the same period being 18.8 in London and 16.2 in Edinburgh. The 130 deaths of persons belonging to Dublin registered during the week under notice were 32 below the number in the preceding week and included seven which were referred to the principal infectious diseases, against eight, five, and seven in the three preceding weeks; of these, three resulted from "fever," two from diarrhoea, one from diphtheria, and one from whooping-cough, but not any from small-pox, measles, and scarlet fever. These seven deaths were equal to an annual rate of 1.0 per 1000, the death-rates from the principal infectious diseases last week being 1.6 in London and 0.9 in Edinburgh. The fatal cases of "fever," which had been two, one, and four in the three preceding weeks, declined again to three last week. The 130 deaths in Dublin last week included 18 of children under one year of age and 41 of persons aged 60 years and upwards; the deaths of infants were 13 fewer than the number in the preceding week, while those of elderly persons showed but a slight decline. Six inquest cases and six deaths from violence were registered, and 56, or more than a third, of the deaths occurred in public institutions. The causes of six, or nearly 4 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

Inspector-General of Hospitals and Fleets Herbert Mackay Ellis, K.H.P., Director-General of the Medical Department of the Royal Navy, has been granted the relative rank of Vice-Admiral in His Majesty's Fleet (dated Jan. 1st, 1906).

In accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1881, Staff-Surgeon Henry Newport Stephens has been allowed to withdraw from His Majesty's Naval Service, with a gratuity.

The following appointments are notified:—Staff Surgeon W. J. Codrington to the *Isis*, on recommissioning; Surgeons: K. D. Bell to the *Isis*, on recommissioning; A. Bradley, lent to Portland Hospital; and W. T. Haydon to the *Actæon*.

ROYAL ARMY MEDICAL CORPS.

Major H. A. Hinge, adjutant of the dépôt and training school at Aldershot, is placed under orders for India. Colonel W. E. Saunders, C.B., R.A.M.C., is appointed to officiate as principal medical officer, Eastern Command, India, *vice* Surgeon-General W. L. Gubbins, C.B., proceeding home on leave. The following officers proceed to India for a tour of service this month: Lieutenant-Colonel A. E. Morris, Captain A. H. Waring, Lieutenant R. H. L. Corder, and Lieutenant R. P. Nash. Lieutenant A. A. Meaden is granted an extension of sick leave until March next. Captain J. J. W. Prescott, D.S.O.,

medical officer in charge of troops and of recruiting. Mutley Barracks, Plymouth.

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 2nd Cinque Ports: Surgeon-Captain C. R. Skyrme resigns his commission (dated Dec. 30th, 1905).

Rifle Corps: 1st Volunteer Battalion, the Northumberland Fusiliers: Surgeon-Major D. Stewart is granted the honorary rank of Surgeon-Lieutenant-Colonel (dated Dec. 30th, 1905). 2nd Volunteer Battalion, the King's (Liverpool Regiment): Surgeon-Lieutenant-Colonel and Honorary Surgeon-Colonel G. Westby (Brigade-Surgeon-Lieutenant-Colonel, Senior Medical Officer, Liverpool Volunteer Infantry Brigade) resigns his commission, with permission to retain his rank and to wear the prescribed uniform (dated Dec. 30th, 1905). 3rd Volunteer Battalion, the Lincolnshire Regiment: Surgeon-Lieutenant-Colonel F. J. Walker is granted the honorary rank of Surgeon-Colonel (dated Dec. 30th, 1905). 1st Volunteer Battalion, the Leicestershire Regiment: Surgeon-Lieutenant-Colonel R. B. Smith (Brigade-Surgeon-Lieutenant-Colonel, Senior Medical Officer, Leicester and Lincoln Volunteer Infantry Brigade) is granted the honorary rank of Surgeon-Colonel (dated Dec. 30th, 1905). 3rd Lanarkshire Volunteer Rifle Corps: Surgeon-Captain T. Forrest, to be Surgeon-Major (dated Dec. 30th, 1905). 3rd (Duke of Connaught's Own) Volunteer Battalion, the Hampshire Regiment: Surgeon-Major E. J. Hunter (Brigade-Surgeon-Lieutenant-Colonel, Senior Medical Officer, Hampshire Volunteer Infantry Brigade), to be Surgeon-Lieutenant-Colonel (dated June 13th, 1904). The undermentioned Surgeon-Lieutenant-Colonels are granted the honorary rank of Surgeon-Colonel:—O. Knott (dated Dec. 30th, 1905) and E. J. Hunter (Brigade-Surgeon-Lieutenant-Colonel, Senior Medical Officer, Hampshire Volunteer Infantry Brigade) (dated Dec. 30th, 1905). 1st (Renfrewshire) Volunteer Battalion, Princess Louise's (Argyll and Sutherland Highlanders): Surgeon-Major T. Philip to be Surgeon-Lieutenant-Colonel (dated Dec. 30th, 1905).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

Lancaster and Border Bearer Company: Supernumerary Surgeon-Captain W. B. Cockill, from the 2nd (Westmoreland) Volunteer Battalion, the Border Regiment, to be Captain, and to command (dated Dec. 30th, 1905).

NEW YEAR HONOURS.

The King has appointed Surgeon-General Richard Browne, I.M.S., Surgeon-General with the Government of Madras, a Companion of the Order of the Indian Empire, and has awarded "the Kaisari-i-Hind Medal for Public Service in India" of the first class to Lieutenant-Colonel Robert Shore, I.M.S. (Bengal), Residency Surgeon, Mowar.

DEATHS IN THE SERVICES.

Captain James Valentine Roche, R.A.M.C., on Nov. 26th, 1905, through injuries received while riding in the recent Army Cup race at Lucknow, India. He entered the service in 1901 and was promoted captain in 1904. He served in the South African war in 1901-02, including operations in the Transvaal, Orange River Colony, and Cape Colony (medal with five clasps). The deceased officer was 29 years of age.

GERMANY AND THE JAPANESE PRISONERS OF WAR RETURNING FROM RUSSIA.

The Japanese newspapers are full of praise for the exceptional kindness shown by the German Red Cross Society to the Japanese prisoners of war, who, to the number of nearly 2000, recently passed through Germany en route for home via Hamburg, after one and a half years' imprisonment in Russia. The German arrangements for the transport and care of the wounded, of whom there were 64, were uniformly excellent. On the Prussian State railways there are four classes of carriages, those of the fourth class being without compartments and having a wooden bench fixed round the interior, the entrances being at either end. For the first time the experiment was tried of fitting up fourth class carriages as hospital wagons with complete success. These carriages are connected with the heating apparatus of the train and therefore make far better hospital wagons than the goods trucks which were formerly used for the purpose and which in winter time could only be heated in an unsatisfactory manner by means of portable stoves. The German Red Cross Society sent men to Wirballen on the Russian frontier to fit up the hospital carriages of the train which was to convey

the prisoners to Hamburg, where they were to embark on specially chartered steamers for Japan. These carriages were provided with beds of the so-called Linz-Weiller pattern placed one above another two deep, like sleeping berths on board ship, and a number of folding-tables, bedroom commodes, and bedpans were also supplied, together with a stock of lint, plaster, and other surgical dressing materials. Some of the men who were very seriously ill, suffering from pneumonia, pleurisy, and tuberculosis, travelled in a darkened carriage and were constantly attended by some of the 53 Japanese Red Cross male nurses who had accompanied the prisoners during their internment in Russia. Eight prisoners suffering from tuberculosis were placed in an isolated carriage and five of this number died before Berlin was reached. The remaining three stayed at Berlin, while their carriage was uncoupled to take them to Grabowsee, where they visited the sanatorium (*Lungenheilstätte*). At each station at which the train stopped on the line between Wirballen and Berlin German Red Cross attendants were waiting with food and delicacies of various kinds for the men. Some of the Japanese were very badly crippled through amputation; one man, indeed, had had both his legs and arms removed and another had lost his foot through frostbite sustained in the terrible severity of a Manchurian winter. This practical sympathy shown by the German Red Cross Society to sick and wounded foreigners passing through Germany is a good illustration of what such societies may do for the relief of suffering, the encouragement of international amity, and the benefit of the world at large.

THE NEW UNDER SECRETARY FOR WAR ON THE ARMY.

We are very glad to notice that the Earl of Portsmouth, speaking last week at a Liberal meeting in Hampshire, intimated that it would be the endeavour of the War Minister and himself to conduct War Office affairs as far as possible on non-party lines. As our readers know, THE LANCET has nothing to do with politics beyond desiring to see, of course, that all questions affecting the medical services and profession have due consideration and lead up to wise and statesmanlike conclusions regarding them. Lord Portsmouth said in the course of his speech that our efforts ought to be to make the army, so far as possible, part of the national life of the country. In its peculiar position, the nation must depend very largely upon its reserve forces which must be properly developed and encouraged. It was the intention of those in power at the War Office to do the best they could for the army, without fear or favour, and without regard to any party considerations.

POST-GRADUATE CLASSES IN MILITARY SURGERY: AN INTERESTING DEPARTURE.

Many members of the West London Medico-Chirurgical Society having expressed a wish for instruction in the special work of military surgeons so that they may be in a position to render aid in time of war, the Director-General of the Army Medical Department has arranged for a short course of lectures and demonstrations to be given at the West London Hospital on alternate Saturdays at 4 p.m., commencing on Jan. 20th. An endeavour will be made to give a broad and practical view of the subject without going too much into detail. Medical men residing in West London, whether members of the society or not, who may wish to attend the course, which is free, are requested to apply by letter to Mr. H. W. Chambers, 101, Goldhawk-road, London, W. The course is under the direction of Colonel H. E. R. James, R.A.M.C., superintendent of the Royal Army Medical College, and the size of the class will necessarily be limited.

TREATMENT OF MILITARY PATIENTS AT EXETER.

The Exeter Sanitary Committee has entered into an agreement with the military authorities for the reception of military patients suffering from infectious diseases at the Exeter Sanatorium. The military authorities are to pay 25s. weekly for each patient, 8s. for the removal or discharge of each case, and in case of death to defray the expenses of interment. The committee reserves to itself the right to refuse the admission of any patient if the sanatorium is full.

Lieutenant-Colonel R. H. Charles, I.M.S., professor of surgery at the Medical College, Calcutta, is specially attached to the suite of the Prince of Wales for his Royal Highness's Indian tour.

In connexion with proposals for the improvement of the food of the soldier, more particularly in the field, it has been decided to form a class for officers at the Army School of Cookery, Aldershot.

Correspondence.

"Audi alteram partem."

THE PROPOSED AMALGAMATION OF THE LONDON MEDICAL SOCIETIES.

To the Editors of THE LANCET.

SIRS,—Dr. G. Steele-Perkins has found a great mare's nest concerning the proposed amalgamation of the London medical societies, about which he wrote to you in your issue of Dec. 23rd last. He would not have done so had he asked any member of the general committee of representatives or any official of the Royal Medical and Chirurgical Society about the scheme. The report to which Dr. Steele-Perkins refers was a preliminary scheme which was referred to the various societies for their views. It was drawn up by representatives of all societies and certainly was not intended to favour any one society. It is the belief that the majority of members will become Fellows that augurs so well for the success of the scheme. On p. 4 it is expressly stated that "every member of the societies which amalgamate shall have the option of joining the new society," and on pp. 2 and 3 a reference is made to the expectation that many who are now only members of the joining societies will become Fellows of the new society.

It is proposed that the property of the new society shall be vested in the Fellows, who will consist at first of all members who are willing to pay 3 guineas annually, and Dr. Steele-Perkins is entirely in error in stating that the only Fellows will be those Fellows of the Royal Medical and Chirurgical Society who have already compounded their subscriptions.

Some of the inconsistencies of the tentative scheme to which Dr. Steele-Perkins draws attention will require consideration and adjustment later when the details will have to be worked out, such, e.g., as to what should be the subscription of a Fellow who has already compounded for an annual subscription of 1 guinea in a society; but these are of minor importance and can be kept till the new society is formed. Further consideration will, I feel sure, convince Dr. Steele-Perkins that his fears are unfounded and they certainly never occurred either to the general committee which drew up the scheme nor to the council of the society referred to that only suggested certain alterations in detail.

I am, Sirs, yours faithfully,

Portland place, W., Jan. 2nd, 1906.

G. NEWTON PITT.

SIR JOHN BATTY TUKE AND THE MEDICAL PROFESSION.

To the Editors of THE LANCET.

SIRS,—The action of Sir John Batty Tuke in leaving the meeting of the General Medical Council on the occasion of the discussion on the Rusholme Dispensary has given rise to a misapprehension which might operate unfairly against his candidature for the Universities of St. Andrews and Edinburgh, and the Medico-Political Committee of the British Medical Association has instructed us to state the facts of the case. These are:—

1. That Sir John Batty Tuke left the meeting by special permission of the Chairman and at the request of the British Medical Association for the purpose of introducing to the President of the Local Government Board the deputation in support of the Public Health Bill prepared by the Association to give security of tenure to medical officers of health.
2. That this had been arranged before it was known that the discussion on the Rusholme Dispensary would be taken at that time.

The Central Council has given instructions that in the case of every Member of Parliament who has conspicuously supported or opposed the policy of the profession in Parliament, and is a candidate, particulars of his action should be furnished to each medical constituent. As this could not be

done by circular in the case of university constituencies, we take the present opportunity of making it known to the profession that Sir John Batty Tuke has supported the British Medical Association on every occasion on which such support has been sought.

We are, Sirs, yours faithfully,

R. O. BUIST,

Chairman of the Medico-Political Committee of the British Medical Association.

G. H. W. PARKINSON,

Chairman of the Public Health Committee of the British Medical Association.

ASSOCIATION OF MEDICAL MEN RECEIVING RESIDENT PATIENTS.

To the Editors of THE LANCET.

SIRS,—There is reason to believe that there are many medical practitioners in all parts of the country, particularly in health resorts, who have facilities for the reception of invalids into their houses for treatment. Such practitioners may not be aware that there has been in existence for some time a coöperative "Association of Medical Men Receiving Resident Patients" which it might be advantageous for them to join. Full particulars may be obtained from the honorary secretaries of the association, 18A, Hanover-street, Hanover-square, London, W., or Bodorgan Manor, Bournemouth.

I am, Sirs, yours faithfully,

Bournemouth, Dec. 23rd, 1905.

G. E. J. ORALLAN.

A CASE OF CLAY-COLOURED STOOLS WITHOUT JAUNDICE BUT ATTENDED WITH COPIOUS BILIOUS VOMIT.

To the Editors of THE LANCET.

SIRS,—After Mr. A. W. Mayo Robson's appeal to exact analyses the letters of Dr. P. J. Cammidge and Mr. F. A. Watkins come as a surprise. One naturally looked for figures, but none are forthcoming. Dr. Cammidge divides his results of analyses into six statements. Before dealing with them it is necessary to recall the precise question at issue. It is this. I have strongly disagreed with the opinion that "the characteristic white stools often seen in pancreatic disease in the absence of jaundice are their pale colour entirely to the solidification of the fat when the motion cools, although there may be a normal amount of bile entering the intestines." (The italics are mine.) With this kept in mind, three of Dr. Cammidge's six statements may be quickly dealt with. No. 1 proves nothing, for the excess of fat and defect of colour may both be due to a common cause, not one to the other. No. 2 proves nothing, for no one has suggested that the pale colour may not be partly due to the quantity of fat present or to its quality. No. 6 also proves nothing, for in such cases also pigment may be diminished.

The other three statements require more detailed scrutiny. No. 5 is indeed a quantitative statement but the essential comparison with the normal is omitted. The first part of this statement also is not in accordance with other observations to which I shall presently allude and the second part is opposed to the statement of Mr. Watkins, immediately below on the same page. No. 3 records a definite and interesting result but is immediately discounted by No. 4. No. 4 is the only instance in which Dr. Cammidge has made the essential comparison with the normal and it is noteworthy that, so far as it goes—for it, too, is incomplete—this statement tends to support my view, not Mr. Mayo Robson's. As the argument used is also the only argument brought forward by Mr. Watkins, which strictly applies to the point at issue, I may consider the two together. In Dr. Cammidge's words, "removal of the fat with ether leaves a residue similar to that obtained from normal faeces." If this means anything relevant to the present discussion it means that this residue contains a percentage of pigment similar to that contained in the residue from normal faeces. If this be so, then in the case cited by Dr. Cammidge, a little further on in his letter, where 90 per cent. of the dry weight of the faeces consisted of fat, leaving only 10 per cent. residue, there must have been a very notable diminution in the output of pigment, unless the faeces were remarkably excessive in bulk, of which no suggestion is made. For normal faeces contain about 15 per cent. of fat and therefore should leave 85 per

cent. of residue. In other words, bulk for bulk, normal faeces should contain, according to the above statement, eight and a half times more pigment than the faeces of this case. Unless, therefore, the fatty faeces were eight and a half times bulkier than the normal the output of pigment must have been less than normal. Does Dr. Cammidge suggest that they were so bulky as this? In the case I lately published their bulk was certainly nothing like so excessive. The statement with which I disagree therefore remains "non-proven," and I still think it mistaken.

On the other hand, the following supports my view. In THE LANCET of May 30th, 1903, p. 1497, will be found a very interesting paper by Dr. W. B. Cheadle on Acholia, defined as a condition of "absence of bile in the stools without jaundice or sign of obstruction to the biliary outflow from the ducts," therefore including all kinds of cases characterised by stools of this description. Analyses of the faeces in Dr. Cheadle's cases had been made by Dr. W. H. Willcox. Dr. Cheadle said, "In all cases bile pigment is deficient and in extreme and typical cases, where the stools appear white, no trace of it can be found. Moreover, in the most marked cases analysed by Dr. Willcox the bile acids were entirely absent also." In one of the cases quoted (Case 2) the stools contained at one time 49.65 per cent. of fat, whilst "bile pigment and bile acids were entirely absent." It is to be observed, however, that this case recovered, so that its exact pathology remains doubtful. Again, there is Sir Lauder Brunton's case quoted by Mr. Mayo Robson in his Hunterian lectures in 1904, in which Dr. Sidney Martin found only small quantities of unaltered biliverdin and "only an indication of biliary acids" in the white motions. The fact probably is that the pale colour of the faeces, in cases such as have been discussed, depends partly on the excess of light-coloured fat present, partly, as Dr. Cammidge suggests, on the crystalline peculiarities of the fat, and partly on a diminution in the output of the faecal pigment. The exact part played by each of these factors is, no doubt, different in different cases. What the real explanation of this diminution in the pigment is cannot be now positively stated. It evidently occurs when abundant bile is entering the alimentary canal. Dr. J. T. Walker's suggestion that defect of pancreatic secretion may have something to do with it is well worthy of attention. There is one thing which, at all events, I think that this discussion has brought out clearly (especially some curious facts mentioned by Mr. Watkins)—viz., that the whole subject of faecal pigment is in need of re-investigation. When that is undertaken I hope that Dr. Walker's theory will not be lost sight of. With apologies for the unavoidable length of this letter,

I am, Sirs, yours faithfully,

Exeter, Dec. 30th, 1905.

W. GORDON.

VENTRAL FIXATION OF THE UTERUS BY A NEW METHOD.

To the Editors of THE LANCET.

SIRS,—If Mr. W. G. Richardson will consult THE LANCET of Feb. 12th, 1898, p. 429, he will find the description of an operation almost identical with the one which he publishes in your columns last week, written by Mr. C. J. Bond of Leicester. This operation I have seen done many times with excellent results both at Leicester and at the Bradford Infirmary.

I am, Sirs, yours faithfully,

Girlington, Bradford, Dec. 27th, 1905.

J. PHILLIPS.

MODERN MEDICAL EDUCATION.

To the Editors of THE LANCET.

SIRS,—I think "L.S.A." is hardly fair in his very sweeping condemnation of modern medical teaching. Nowadays, certainly, the enormous amount of knowledge which can, and must, be obtained solely by clinical work under the guidance of a properly qualified teacher has tended to crowd out "treatment" from the systematic courses of study pursued in the medical schools. The courses of study pursued in the medical schools, by medical registrar, hammering away at the methods by which disease is recognised and differentiated—and which disease is recognised and differentiated—and "L.S.A." will himself admit that it is as well to have some

sort of an idea of one's patient's ailment before the administration of any drug—has little or no time to deal with the treatment of the particular case, and the student recognises this. He is also aware that the examiners at the colleges and the universities have an awkward habit of following up their examination-in-chief by the question "And how would you treat it?" As ward clerks this was common knowledge to us, and we applied the remedy by following our own, and other, house physicians on their morning rounds. We saw what was given, what happened or what did not happen, and we asked the reason.

The house physician, being a man who was endeavouring to make the most of his time, welcomed the amateur censorship and found that the necessity for explanation implied a corresponding necessary cogitation before applying any of the pharmaceutical remedies of his calling. If the physician, on his rounds, saw fit to change the treatment, he was forced, if merely in justice to his house physician, to explain why he had done so to his class. So it arose that the house physician taught treatment.

I am only a recently qualified general practitioner and therefore hasten to bow to the undoubted practical experience of "L.S.A." Still I cannot agree that the Apothecaries' Hall examinations demand a greater knowledge of drugs and their applications than the tests applied by other examining bodies. I have the M.R.O.S., L.R.C.P., and the B.S. and M.D. Lond. I have not taken the L.S.A. but I have successfully "coached" for that diploma. I have held the usual appointments, including house physician at a great London hospital, and can therefore place myself on all fours with "L.S.A.'s" son. Yet I should be false were I to deny the enormous amount of practical treatment that I learnt in my various appointments.

As a house physician I did not have to worry with blood counts and the like. They were the province of the clinical clerks. I was therefore free to apply myself simply and solely to treatment, and this I hold is one of the inestimable advantages of a house physicianship at a big hospital. In my turn I had my volunteer class of fifth years' men and we argued and wrangled over treatment. I had to be sure of my facts; I was always liable to the direct negative from one of my "class" and it was never policy to attempt to bluff. Anything new was given a fair trial and dropped or continued according to results.

I admit there is a class of men which considers that the ends of medical science are met when once the lesion is located with accuracy. But this class is small and learns wisdom later. The great bulk of students at the present time fully realise the importance of treatment and do their best to acquire some working knowledge. As to the house staff, how often has one heard the caution from one house physician to another who is filling his friend's spare beds: "Don't send me in any curiosities. Send me in something I can treat." Apologising for a prolix and, I fear, egotistical letter,

I am, Sirs, yours faithfully,

Jan. 1st, 1906.

GENERAL PRACTITIONER.

THE BATTLE OF THE CLUBS.

(FROM OUR SPECIAL COMMISSIONER.)

Medical Scandal at Macclesfield.—Local Economic Conditions.—No Improvement for Three-quarters of a Century.—Medical Officers paid 10d. per Member per Year.—Contract Work at Less than a Farthing per Week.

OF all the deplorable descriptions of the degradation wrought in the ranks of the medical profession by club practice or the contract system the following account of the state of affairs at Macclesfield will probably rank among the worst. This town used to be a prosperous silk manufacturing centre and some 75 years ago an individual called Fergusson started a burial club for the advantage of the operatives engaged in that trade. Any student of political economy knows what were the conditions of the workers in factories during the earlier half of the nineteenth century; how the abuses then prevalent led up to the Chartist agitation, to the Peterloo massacre, and finally resulted in far-reaching and beneficent factory and sanitary legislation. It was on July 10th, 1831, that the Macclesfield General Burial Society was established and on Jan. 11th, 1905, this society issued its seventy-third annual report and balance-sheet. It had 6115

members in 1904. Then there is a Burial Society No. 2, which has 5300 members and was established in 1833. In the face of these dates it is only natural to observe that contracts made with members of the medical profession three-quarters of a century ago cannot be considered as satisfactory under the altered conditions which prevail to-day. What club practice was when first these burial societies were created I am unable to say, but a graphic description was given to me by an old resident of how the system worked some 40 years ago. In those days the burial clubs employed two elderly practitioners who had seen some 60 summers. Then there was an army surgeon who was going downhill very rapidly and another practitioner who was a perfect gentleman. Everyone spoke well of the latter; his manners were unimpeachable, he was a general favourite, but he was almost always drunk. He was much in demand in cases of accouchement. All that was necessary was to send for him in good time, provide a sofa so that he might lie down and have a sound sleep, have a cup of strong tea ready for him when he awoke, and then he would be able to attend to the case with the greatest skill while charming everyone by his extremely refined, courteous, and agreeable manners.

In those days unqualified assistants were allowed and wonderful stories are told of their prowess and popularity. The curious thing is that at least one of these unqualified assistants seems to have had a better sense of standing up for his rights than the medical men engaged in the same service. He did think that the extent to which he should be exploited by the burial societies should have a limit, so he refused to go out or to see any patient after 8 P.M. Thus he left the night work for the fully qualified practitioners. Then there was another assistant who had been taken out of one of the mills. He was an uneducated workman, but in time he picked up a little knowledge, became very popular, and it is said that he attended more midwifery cases than any qualified practitioner in the town. Such was the state of club practice at Macclesfield some 30 or 40 years ago, and the younger practitioners when they saw that the club work was in the hands of such men thought that they would leave it to die a natural death. This, however, was a great mistake, for when the elderly medical officers died the burial clubs imported new and more active men who strengthened their position. Also the hopes of improving the conditions of club practice were soon to be gravely affected by the decline of the silk trade. This commenced in 1850 and it became evident that in England, where there are no silkworms and no silk, the industry could not compete with more favoured localities such as Lyons. Practically silk-throwing is dead, the hand loom no longer pays, and at Macclesfield imported manufactured silk can be bought for about the same price as the raw material. Indeed, Macclesfield would have been completely ruined but for some efforts that were made to start other industries. There are some shirt manufacturers and foreign silks are converted into blouses but this is all work for women and, indeed, at Macclesfield the women have far better opportunities of working than the men. There is, it is true, one cotton mill which employs men and women. In these circumstances, of course, the wages earned are very low. Women are always underpaid and the competition between the men for the little work that they can do is so keen that there is no difficulty in keeping their wages down, excepting, of course, the one instance where the well-organised cotton trade is concerned.

Not only are wages much lower and a great number of the men permanently unemployed but it is urged that provisions are much dearer. This, of course, is quite contrary to the experience of large towns such as London, Liverpool, &c. But in a rural district the poultry, eggs, milk, butter, and the meat from the local killing can now, with the aid of the railways, be sent to other than the local market, and therefore those who used to live on what was produced in their immediate vicinity would find living dearer. In any case this is one of the arguments given to explain why the medical practitioners of Macclesfield had not succeeded in improving their position. There was one short period, however, of extraordinary prosperity; this was during the Franco-German war of 1870-71. The French silk trade was then paralysed and orders flowed into Macclesfield. The trade went up by leaps and bounds. Many manufacturers abandoned their legitimate business and launched forth in all manner of new branches, which was imprudent for the boom was not likely to last long. Workmen at that time were sometimes able to earn as much as

£2 in three days and a few found this sufficient to enable them to devote the remaining four days of the week to drinking. There was not much work for the club medical officers to do at that time as the work people could all afford to consult private practitioners and to pay proper fees. The club medical officers, therefore, did not complain because they received the same pay and had less work. The independent practitioners did not complain because they had a large increase of private patients. Both the one and the other failed to see that it was during this period of great prosperity that a successful effort might have been made to improve the conditions of contract work. The golden opportunity was lost, the Franco-German war came to an end, the silk looms at Lyons began to work again, the trade once more left Macclesfield, and it has gone down and down ever since. Thus matters have remained as they were and there has been hardly any change whatever.

Now that I have reached the point when I can no longer defer stating what is this position that has not been altered during so long a course of years, I feel overwhelmed with all manner of doubts and hesitation. It seems so utterly incredible that I find it very difficult to believe the evidence before my eyes and therefore can hardly expect others to do so. In the course of these investigations a few clubs have been discovered here and there which pay their medical officers 3s. and sometimes only 2s. 6d. per member per annum, though 4s. or 4s. 4d. is generally considered the minimum. What, then, can be said of Macclesfield? Will it be credited that at Macclesfield the medical officer of the General Burial Society receives from each member of this club, whom he is bound to attend in case of sickness, a payment of only 10d. per annum! Yet here is the proof of this astounding fact. The burial club in question has printed and issued its seventy-third annual report. This official document is dated Jan. 11th, 1905, and contains on the third page the following: "Number of members at the end of 1903, 6212; joined, 148; withdrawn, 142; died, 103; leaving a total membership of 6115." Then the accounts for every quarter are published, followed by a summary of the whole year. From these it appears that the medical officer was paid £254 13s. 7d. This is equal to 61,123 pennies. If these pennies be divided by the 6115 members it will be seen that it comes almost precisely to 10d. per member. Burial Society No. 2 has also published a report for the year 1904. This is its seventy-second annual report and it states that its medical officers were paid the sum of £200 2s. during the year. Unfortunately, there is no account given as to the total number of members belonging to this society but I am very creditably informed that there are 5300 members. If this is correct then the rate of payment for medical attendance on the members of Burial Society No. 2 is even lower than that of the General Burial Society. The sum paid, £200 2s., is equal to 48,028 pennies, which, divided by the 5300 members, make almost precisely 9d. per annum per member. For each 9d. the medical officer has to be responsible for the supplying of proper medical attendance during an entire year to the individual who has disbursed the 9d. For less than 1d. a month, indeed, for only 3d. per month, the medical officer is day and night at the beck and call of the individual who pays him less than 1d. per week. If that individual chooses to fancy that there is something the matter with him the medical officer is obliged to see the supposed patient as often as may be necessary.

How medical men could possibly have been induced to assent to such terms seems as incredible as it is difficult to explain. Probably these terms were accepted when economic conditions were utterly different to what they are now and have never been altered since. In most societies and even in the case of speculative insurance companies where medical aid is provided the members are charged 1d. a week for such aid and this over and above the subscription which they pay for other benefits, such as sick allowance, burial allowance, &c. These Macclesfield societies, however, work on the basis that 1d. a week is to cover everything and even then they give their members four weeks' holidays per annum. Therefore, there are only 48 collections of 1d., which makes 4s. per annum, instead of the usual 52 weekly collections, yielding 4s. 4d. in the year. Then, the system was to have so many collections for each purpose. Thus in 1904 the General Burial Society had 52 collections for their burial account, ten collections for their medical account, and six collections for their management account.

As the payment is 1*d.* per week the fact that there were ten collections for the medical account helps to confirm the statement made above that the medical officer only receives 10*d.* a year for each person whom he has on his books. If in spite of the smallness of the sum the total income from this source amounted, as already stated, to £254 13*s.* 7*d.*, this is only due to the fact that the medical officer had more than double the number of persons on his books than should be allowed. This, indeed, it is that constitutes the principal danger and scandal of the system. For anything like an income to be made by a medical practitioner when each person on his book contributes less than 4*d.* per week, the number of persons so inscribed must of necessity be far greater than any one medical practitioner can attend properly. Therefore, is it not a degradation of the profession to accept such conditions? Might not the question be put to the General Medical Council? Is it not "infamous in the professional sense" for a medical practitioner to contract to attend professionally on members of a club whenever called if the remuneration given is only equal for each person to about three-quarters of a farthing per week? What sort of professional dignity can a medical practitioner maintain towards a patient from whom he accepts a payment of three-quarters of a farthing per week? Does not the dignity of medical science make it imperative that such terms should be refused and treated as an insult offered to the profession.

(To be continued.)

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Hospital Sunday Fund.

THIS year's collection for the above Fund reaches a total which has only been surpassed once—viz., in 1878, when a special collection was made for the Queen's Hospital. This year's collection totalled £5900 0*s.* 7*d.* Church collections, exclusive of allocated donations and subscriptions, amounted to £4667 7*s.* 6*d.* and specially allocated donations to £1119 4*s.* 7*d.* Of the special allocations £244 14*s.* 8*d.* went to the Queen's Hospital and £202 0*s.* 6*d.* to the General Hospital. The expenses of the collection were £396 18*s.* 7*d.*, leaving an amount available for distribution of £5503 2*s.* The Lord Mayor, in moving the approval and adoption of the accounts, deprecated the practice adopted by a few congregations of ear-marking some portion of the collection as a subscription for which tickets were expected from the charities. He ventured to say that the more collections were handed over as an entirely free gift without any conditions the more the original object for which the fund was established would be carried out. He also thought that another year more consideration should be shown to the minor charities, that the amounts by which some of these benefited were not commensurate with the good that they were doing. The honorary lay secretary in reply to a question stated that the whole collection should be treated as a free gift from the churches of the city to the hospitals in recognition of the work they did. No tickets were to be expected in return for the collections.

Birmingham Distress Committee.

The general purposes subcommittee of the statutory distress committee has met and has decided to open a municipal labour bureau and to invite the unemployed to register their names. Arrangements have been made with the estates committee and the drainage board to employ as many men as work can be found for. The total number of applicants up to date is 538. This number out of a population of more than 500,000 is by no means large and seems to indicate that the amount of distress in Birmingham is not so acute as it is in many other towns. It should, however, be stated that only those unemployed are registered (1) who are willing to work but are temporarily prevented by causes over which they have no control; (2) who are of good character; (3) who have been resident in the city for the past twelve months; and (4) who have not received Poor-law relief within that time. The vast majority of the applicants are outdoor workers and unskilled labourers. Only one woman, a charwoman, has applied. The distress committee at Smethwick has decided to open a stoneyard in committee for the unemployed. It has already received 70 applications for relief.

Coventry and Warwickshire Hospital.

The annual report of the Coventry and Warwickshire Hospital states that 995 in-patients had been treated during the year, as against 913 in the previous year, and 8314 out-patients, as against 8269. There has been a great strain on the accommodation of the institution and in view of that there is an urgent need for greater capacity. For the extension scheme the authorities have already got £11,000—about one-third of the money required. An appeal was made for further annual subscriptions. There had been a notable increase of £325 in the amount received from the Hospital Saturday Fund. The Earl of Craven was elected president in succession to the late Lord Leigh.

Treatment of the Feeble-minded in Birmingham.

The Birmingham, Aston, and King's Norton joint Poor-law establishment committee has adopted a scheme for the treatment of epileptics and feeble-minded. It proposes to erect at once three houses for women and three houses for men, each house to accommodate 36 patients, a total of 216. With a few alterations and the addition of a suitable kitchen Mounthall Hall can be made to serve as "administrative quarters" until the number of patients at the colony exceeds 210. The complete plans provide for seven houses for women and seven for men.

Welsh Water and Galvanised Kettles.

The health committee of the city council has had under consideration certain galvanised kettles which are now in common use throughout Birmingham. The medical officer of health has made investigations and has found that any pure soft water acts on these kettles with great vigour and dissolves so much of the zinc from the galvanising as to make the water harmful and objectionable. The committee has passed a resolution approving of two circulars which the medical officer of health has been instructed to publish. The first is to be sent to kettle manufacturers asking them to call in any kettles which they may have distributed with a view of preventing the sale of them within the city, and the second circular is to be sent to ironmongers and others requesting them not to sell any kettles having a galvanised zinc coating. Enamelled or tinned kettles are recommended by the committee but from some correspondence in the local papers it would seem that the former are also open to objection.

The Birmingham Rowton Houses.

The third annual general meeting of the shareholders of the Birmingham Rowton Houses, Limited, has lately been held at the Rowton House in Moseley-street. The report for the year stated that the daily average number of residents in March was 317, while in October it was 630. The profit for the first seven months was £694 16*s.* 11*d.*, and the directors hoped, but did not promise, that they would be able to pay a dividend next year. The directors intend to start a midday dinner and will supply a first-class meal at a cost of 6*d.* A weekly series of concerts has been instituted and has been greatly appreciated by the residents. It was mentioned that the men whom they got in the house were very similar to those in the London houses except that the Birmingham men were particularly fond of cooking their own food.

Jan. 2nd.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Public Baths.

FOR many years Manchester has been interested in making provision for bathers and when the Victoria baths and the Moss Side baths are completed there will be 25 swimming baths, 497 wash baths, three Turkish baths, one Russian bath, and two public wash houses. Although a port Manchester cannot boast of the fitness of her waterway for swimming exercises. There are no sheets of water available, so that the youths of the city have to make use of the baths if they want to learn to swim. The total capital outlay by the corporation on these baths has been £157,798. This is exclusive of the expenditure on the Gorton, Newton Heath, and Whitworth baths before the respective districts became included in the city. The cost of the Victoria baths, £40,654, and of the Bradford baths, £3811, has also been excluded. There were 1,220,472 bathers for the year ending Sept. 30th, an increase of more than 31,000 as compared with

the previous year. No new swimming baths were opened between 1897 and 1905 and during that time the number of bathers has increased from 133,152 to 575,180. The number of school children using the baths increases year by year and many learn to swim. The proportion of the population who can swim will compare favourably with that of many places on the coast. There are life-saving classes and awards are given in the shape of season tickets. Last year 342 awards were given as against 582 in 1904. The cause of the decrease last year is not apparent. Appeals continue to be made still from some of the populous districts for baths and wash houses on more modest lines than the costly—many think far too costly—buildings on which tens of thousands of pounds have been lavished. It is good that Manchester should be well provided with swimming baths, for it is a smoke-begrimed city, but the actual possibilities of cleanliness for the men, women, and children of the crowded tenements in the "mean streets" and for the cleansing of their malodorous clothing are better met by the more humble, but for them more useful, cottage baths and wash houses which these poor folks can enter without shame and shrinking.

Requests to Medical Charities.

It was mentioned a short time since that Mr. A. W. Mills, a well-known architect in Manchester, left £4000 to the Owens College for a permanent endowment, this, of course, not being strictly medical, and £3000 to the Manchester Royal Infirmary and Dispensary. He also left £500 each to St. Mary's Hospital, to the Altrincham Provident Dispensary, to the Manchester Hospital for Consumption and Throat Diseases, and to the Hospital for Incurables at Mauldeth Hall. Besides these bequests to medical charities, he left £4000 to the Manchester Grammar School for scholarships for boys, tenable at Oxford or Cambridge, and £500 to the Architects' Benevolent Society.

Workhouse Inmates and Razors.

An inquest was held on Dec. 28th, 1905, on the body of a man who had been in hospital since June suffering from pulmonary tuberculosis and on Christmas Day attempted to cut his throat with a razor. The medical officer said that the slight wound in his throat had no effect in hastening the man's death which was due to pulmonary tuberculosis. The master of the workhouse stated that it was against the rules of the house for inmates to shave themselves. Razors, knives, or anything of the sort were taken from them but it was impossible to prevent friends giving them razors which they hide. This seems likely enough when, as the master said, on one occasion there were nearly 2000 visitors. The point of interest in this case is the suggestion that the attempt at suicide might have been brought about by a sad occurrence that took place recently. A nurse was suspected, rightly or wrongly, of stealing and committed suicide by throwing herself from a window, and the coroner asked the medical officer if he thought it had had any effect on the patients. Dr. Wright replied that it might have preyed on the minds of a few. He further said, in reply to the coroner, that the officials would take all possible precautions.

Anthrax at Bradford.

The importance of perfecting the processes for the disinfection of the raw materials containing the germs giving rise to anthrax is emphasized by the fact that this disease has caused seven deaths at Bradford within a few weeks. There have never been so many cases in so short a time in Bradford.

LEEDS.

(FROM OUR OWN CORRESPONDENT.)

Leeds Public Dispensary.

THE election committee of the Leeds Public Dispensary has made the following appointments:—Honorary surgeon in charge of diseases of the throat and nose, Mr. A. D. Sharp, M.D. Birm., F.R.C.S. Edin.; honorary medical officers in charge of medical cases, Mr. Sydney Clark, L.R.C.P. Lond., M.R.C.S. Eng., and Mr. J. Gordon Sharp, M.D. Edin.; honorary medical officers in charge of surgical cases, Mr. W. McGregor Young, N.A., M.D., C.M. Glasg., and Mr. A. Mackenzie, M.A., M.B., D.C. Cantab. The four last-named gentlemen will be in charge of the southern branch of the

institution which is to be developed as a consequence of the taking over of the Southern Dispensary by the older institution.

A Point in the Sale of Poisons.

The decision of the Leeds stipendiary magistrate in regard to the sale of Rankin's ointment, which contains veratrin, has not been sustained on appeal to the Divisional Court of the King's Bench Division. The stipendiary pronounced his reasoned judgment on May 2nd and in convicting the defendants he stated that it had been established by a series of decisions culminating in a judgment of the Court of Appeal that the statute applied in the case of a mixture or compound where a scheduled poison constituted one factor in the composition of the article sold. He declined to accept the argument that all vermin-killers, whatever their constituent poisons, must be deemed to be in Part II. of the schedule, and held that it was consistent with the resolution of the Pharmaceutical Council in 1869 to hold that vermin-killers containing poisons in Part I. fell within Part I. For the defence it had been contended that compounds containing poisonous alkaloids did not come within Part I. of the schedule of the Act but were within Part II. and could therefore be sold to an unknown person if properly labelled "poison." The Lord Chief Justice, while agreeing that in certain cases the selling of a compound containing a poison was the same as selling the poison itself, considered that in this case the compound in question came within the second part of the schedule and he ruled that the conviction could not be maintained. Justices Lawrance and Ridley concurred and the appeal was allowed with costs. The judgments of the Leeds stipendiary in the cases of the selling of Easton's syrup, which he pronounced on the same date as the above, and against the defendants, have not been challenged and stand. In one of these cases it had been argued for the defence that Easton's syrup was nothing but a medicine and that it was "dispensed," because it was made up at the customer's request from Dr. Easton's prescription. The customer was, however, requested to sign the poison register. In the remaining two cases this request was not made. It is difficult for the non-legal mind to follow the reasoning which led to an appeal in the first class of cases—the Rankin's ointment cases, that is to say—and yet did not lead to an attempt to upset the judgment in the first case of the second group. Here the defence seems indeed to have been inconsistent, for if the chemist was merely "dispensing," as it was maintained, why was the customer called on to sign the poison book? The stipendiary found that the sale was not an act of dispensing and therefore this case looks very much on the same footing as those concerned with the sale of Rankin's ointment and one therefore in which the judgment might have been reversed on appeal.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Memorial to the late Dr. William Turnbull.

In a previous letter (July 29th, 1905) attention was drawn to the proposed memorial to the late Dr. W. Turnbull, formerly demonstrator of anatomy in the Durham University College of Medicine. The brass tablet then mentioned has now been appropriately erected in the dissecting-room, the scene of Dr. Turnbull's earnest labours. The inscription reads as follows:—

In Memory of
William Turnbull, M.B., B.S.,
Demonstrator of Anatomy in this College,
1835 to 1903.
Died Sept. 20th, 1903, aged 42 years.
This Tablet is erected by Fellow
Students and Friends.

The Borough of Tynemouth Water Scheme.

For many years past the water-supply of Tynemouth and district (the largest town in the area is North Shields) was in the hands of the North Shields Water Company but for a quarter of a century the Tynemouth corporation was unable to obtain water from the company for watering the streets, flushing sewers, and other sanitary purposes, and even the domestic supply was often inconveniently curtailed. To make amends for these too numerous deficiencies an extra supply had to be obtained from the Newcastle and Gateshead Water Company, but this could

only be secured under various restrictions under the special Acts of that company and, of course, at very considerable cost. Under the yoke of these disadvantages several attempts were made to place the Newcastle company under statutory obligations to supply the Tynemouth borough, but the Newcastle company was joined by the corporations of Newcastle and Gateshead in active resistance to any such scheme. Thus the Tynemouth borough had no alternative but to secure an independent supply. Accordingly in 1897 the corporation acquired the old company's works and in the following year procured from Parliament power to proceed with the scheme which is now being actively pushed forward. The Font is a mountain stream of pure water which flows down from the hills to join the river Coquet a few miles below the town of Rothbury. This stream is being dammed to form an artificial lake, the water from which has to travel a distance of 25 miles to the distributing reservoir at Moor House, near North Shields. The works at the Font include filter-beds and the long line of pipe-track necessary. The contract time for the completion of the works is July, 1907, but it is confidently expected that they will be in working order before that date. Already the borough is receiving overflow water to the extent of half of its daily supply and in wet weather the excess is enough to effect a saving of something like £100 a week in the lessened quantity required from the Newcastle Company. Financially the scheme is a costly one, having already involved expenditure amounting to £415,900, and the total is expected to reach £500,000 before completion of the work, this representing the cost for a rateable area of 63,000 inhabitants. To make the scheme a monetary success it will be necessary to sell the surplus water to the many small towns and villages within the possible supply area, including Ashington, Morpeth rural, Newbiggin and Tynemouth rural districts, and to this end terms are now being discussed. It is calculated that if all the surplus water be sold it will amount to an available profit of £4000 per annum, which would mean a reduction of 5½d. from an otherwise necessary 8d. water-rate.

Lecture on Aphasia and Cerebral Speech Mechanism.

On Dec. 7th Dr. Byrom Bramwell visited Newcastle-upon-Tyne as the guest of the Clinical Society and delivered in the College of Medicine a very well-attended lecture on Aphasia and Cerebral Speech Mechanism. The lecturer did not belie his reputation and delighted his large audience with a clear and highly interesting dissertation on this difficult subject, deriving much aid in making points clear by reference to a series of ingenious diagrams which he had brought with him. In moving a vote of thanks Professor George R. Murray said he had been privileged to hear many notable authorities lecture on aphasia, both in this country and abroad, but he had never listened to a more lucid disquisition. He also claimed some of the credit for the Newcastle School on the ground that Dr. Bramwell's study of the subject had been begun when he acted as physician to the Royal Infirmary in Newcastle. In seconding the motion Dr. Thomas Beattie remarked on the stimulating effect of such an address on those privileged to hear it. In reply, it was with no little feeling that Dr. Bramwell referred to his early connexion with Newcastle, and he went so far as to confess that he had often doubted the wisdom of the step he took when he left it. In the evening the guest was entertained at dinner at the County Hotel, there being a very large attendance.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Death of Mr. M. H. Greener, M.B., C.M. Glasg.

THE death of Dr. Michael Hindmarsh Greener on Dec. 26th, 1905, came as a great shock to the medical profession in Cardiff. He succumbed to an attack of broncho-pneumonia after an illness of less than a week's duration. Born in Alnwick in 1858 he graduated as M.B. and C.M. at the University of Glasgow in 1884 and almost at once began to practise in Cardiff. He was on the staff of the Cardiff Provident Dispensary and was honorary medical officer of the convalescent home at Dulwich House. He was buried at Dinas Cross in Pembrokeshire, where he had built a house and usually spent his holidays. He leaves a widow, a son, and a daughter to mourn their loss.

Legacies to Bristol Hospitals.

Miss Matilda Mercer of Clifton has left sums of £1000 to the Royal Infirmary and General Hospital, Bristol, and £200 to the Bristol Royal Hospital for Sick Children and Women and to the Clifton Dispensary. Subject to the life interest of her sister the Royal Infirmary and the General Hospital will each benefit to the extent of £4000; the Women and Children's Hospital will receive £1500; the Queen Victoria Jubilee Convalescent Home £3000; the Weston-super-Mare Sanatorium, the Bristol Orthopedic Hospital, and the Bristol Eye Hospital £1000 each; and the Clifton Dispensary £500.

Poor-law Relief in Bristol.

Reference has already been made¹ to the increasing amount of pauperism in the city of Bristol. The recommendations of a special committee appointed by the board of guardians to consider the question were discussed at a meeting of the board held on Dec. 29th. It was decided to establish a new relief depot and to increase the number of the relief committees with a view to make closer inquiries into the circumstances of applicants for relief. The proposal to appoint a superintendent relieving officer at a salary of £175 per annum was, however, negatived by 36 votes to 17 in spite of its advocacy by the Local Government Board inspector (Mr. E. B. Wethered) who was present at the meeting and who compared the cost of pauperism in the Bristol and Aston unions. The population of the former is 339,000 and of the latter 312,000. During the six months ending March 25th last the in-maintenance in Bristol cost £16,047 and in Aston £10,877, while during the same period the Bristol out-relief cost £20,759 and that at Aston only £4303.

Poor-law Guardians on the Vaccination Acts.

The subject of vaccination is frequently discussed at meetings of the Poor-law guardians in the West of England and at the meeting of the Devonport board held on Dec. 29th it was decided by a large majority to support the resolution which the Runcorn union is sending to the Local Government Board urging that "the principle of vaccination and revaccination in force before the Vaccination Act, 1863, came into operation should be reverted to."

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal College of Physicians of Edinburgh.

At the last ordinary meeting of the Royal College of Physicians of Edinburgh Dr. John Playfair was re-elected President of the College, Dr. Thomas S. Olouston, Vice-President, and Sir Thomas R. Fraser, Sir John Batty Tuke, Dr. Charles E. Underhill, Dr. James Ritobie, and Dr. R. W. Philip were elected to the Council with the President and Vice-President. The Council subsequently made the following appointments for the ensuing year: Dr. Peter A. Young, treasurer; Dr. Harry Rainy, secretary; Dr. D. Berry Hart, librarian; and Sir John Batty Tuke, curator of the research laboratory.—At an extraordinary meeting of the College held on Dec. 19th, the College unanimously appointed Dr. James O. Affleck and Dr. Charles E. Underhill to be representatives of the College on the board of management of the Royal Infirmary.

Two Glasgow Medical Practitioners Sued for £20,000.

It is with considerable interest that the medical profession in the West of Scotland has watched the progress in the Court of Session of an action brought against two Glasgow medical practitioners, and the verdict has been hailed with a certain amount of relief, although it is difficult to see how it could have been otherwise. The action was raised at the instance of a Clyde pilot who sued Dr. Marion Gilchrist, a practitioner in the West-end of Glasgow, and Mr. John Carswell, an expert in lunacy of the same city, for £10,000 each for alleged unprofessional conduct in granting certificates to the effect that the pursuer was of unsound mind and thereby causing his incarceration in Gartnavel Lunatic Asylum from September, 1903, to January, 1904. The pursuer's case was that the defenders acted negligently and unprofessionally and made no independent or adequate inquiry into the pursuer's statements or ascertained definitely the pursuer's mental condition and that they did not consult his own

¹ THE LANCET, Dec. 23rd, 1905, p. 1662.

medical adviser. Evidence was led at considerable length and amongst other witnesses two medical men, one of them Sir Henry D. Littlejohn, were called by the pursuer to give evidence as regards his sanity. The case dragged over many days and heavy expenses were incurred on both sides. Lord Pearson, before whom the case was tried, gave his decision to the effect that the certificate was not granted wrongfully or without due inquiry and examination, and that on the various dates on which the pursuer was separately examined by the defenders the pursuer was insane and suffering from an attack of subacute mania with homicidal tendency and was a proper patient for admission to, and detention in, Gartnavel Asylum. Although after the evidence on both sides had been heard there was no doubt in anyone's mind as to what the decision would be, yet there is reason for satisfaction that Lord Pearson in the terms of his judgment took up a position so precise and definite. Such a judgment is of the first importance to the public and to the medical profession. With the public, in its desire to safeguard its own interests and liberty, one has every sympathy, but with the medical practitioner in the discharge of duties of this kind one has still more sympathy. Had the decision in this case gone otherwise the medical practitioner dealing with a case of lunacy would have been on the horns of a dilemma. To grant a certificate might mean being sued for £10,000, while to withhold it, as would be his natural inclination, might mean a worse catastrophe in the shape of homicide, in which case he would not be held blameless. Dr. Gilchrist and Mr. Carswell are to be congratulated on the verdict in what must have been to them a very annoying and expensive lawsuit.

Population of Glasgow.

Dr. A. K. Chalmers, the city medical officer of health, has just issued his annual report with reference to the population of Glasgow. It is of an exceptionally interesting nature and deals at considerable length with the remarkable displacement that is going on throughout the city and suburbs. A significant fact mentioned is that the population of the city within the municipal area as at June last was 785,474, compared with 785,465 for the corresponding date in 1904, representing a difference of nine persons only in favour of the present year. In other words, the population has only been saved from a numerical reduction by reason of an increase in the number of persons resident in institutions and in consequence removed from opportunities of discharging many of the responsibilities of citizenship. This is the first natural interruption to a period of growth which has been continuous since 1887. It is noteworthy that in many of the suburban wards, on the other hand, there is a distinct increase. The depletion of the central districts is no doubt in large part due to increased facilities in travelling which enable the working man to live at a greater distance from his work and from the point of view of the general health and well-being of the community it is not to be deplored.

The Post Office and Bacteriological Specimens.

Recently an order was issued by the Postmaster-General in which conditions were laid down for the transmission by post of articles sent for medical examination or analysis. It is thought that one of these conditions will render useless all the arrangements of the sanitary department for expeditious dealing with the material sent for bacterial examination. A subcommittee has been appointed by the Glasgow corporation to take such steps in the interests of public health as may be thought advisable.

ON Christmas Day Dr. J. C. Martin, on his home-coming after a protracted illness, was presented by his numerous friends in Portrush with a silver casket suitably inscribed and containing 250 sovereigns.

Health of Belfast.

At a meeting of the city corporation of Belfast, held on Jan. 1st, reports were read which indicated, as the chairman of the public health committee stated, "that the present state of affairs in the catchment area (at Stoneyford water

reservoir) was a menace, but the corporation were not the sanitary authority for the district and they had no power to put the law in force." It appears that liquid matter from a manure heap at a farmhouse in the Stoneyford catchment area "flows over the surface of the ground into a water-course; at the other side of the dwelling house the cowshed is situated within a few feet of the stream. This stream is part of the Belfast water-supply" (report of inspector). In reference to a national school in the same district: "The privies are situated over an old watercourse which connects with a small stream that forms part of the Stoneyford water-supply. The liquid matter from the privies gets into the watercourse." Then as to another house: "There is a large quantity of manure lying on the brink of a stream; the liquid filth is flowing into the stream. This is a bad case of pollution. The cowshed, dwelling-house, and premises are in a filthy state." The inspector adds: "I may say I have made reports on above houses at intervals during the past seven years and the sanitary state of the premises is as bad as ever it was." One of the water commissioners present said that not a single drop of the impure matter got into the water-supply of Belfast. The water commissioners were not, in his opinion, to do Li-burn work (the catchment area is in the Lisburn district). It was not, he said, really their business whether these farms were in a sanitary condition or not. That was the duty of the local authority having charge of the district. In other words, a vile nuisance may exist in one of the catchment areas supplying the citizens of Belfast with water and typhoid fever may arise, as it did before, and owing to some small detail as to who has authority over the district hundreds of lives may be lost. It is hoped, as it was suggested at the council meeting, that the Local Government Board will interfere and order an inquiry and place the blame upon the proper authority. It is believed by many that the great epidemic of typhoid fever in Belfast several years ago took its origin from cases that were proved to have existed in this same catchment area, though the excuse then was, as now, that nothing got into the water reservoir. During the four weeks (Nov. 19th to Dec. 16th) reported upon to the city corporation of Belfast on Jan. 1st it was stated that the number of cases of infectious diseases notified was more numerous than in the last report, and while cases of typhoid fever and simple continued fever (whatever nondescript is meant by continued fever) have considerably increased, those from scarlet fever and erysipelas have decreased. Owing to the mildness of the season deaths from chest diseases still keep lower than usual. The death-rate was 20.1 per 1000 and considering the time of the year the health of Belfast may be described as fairly satisfactory.

Royal University of Ireland.

Judge Shaw, who has been a representative of Convocation on the Senate of the Royal University for the last 20 years, has written to the clerk of Convocation resigning his position, on the ground that "he cannot remain a member of a governing body which is liable to be defied and insulted by those whom it is supposed to govern and which either has, or believes it has, no power to repel or punish such defiance and insult."

Hygienic Measures at Cherbourg.

THE admiral who is the maritime prefect of Cherbourg has recently issued an order containing the following regulations for the observance of hygienic measures. Firstly, it is of the greatest importance to prevent men by every possible means from drinking at the standpipes (*bornes-fontaines*) in the arsenal, the dockyard, or the town. In the arsenal the various shops will be supplied with distilled water from the ships in the port which will be sold off for such duty by the naval officer in charge (*major-général*). Depot No. 1 will supply boiled water to men working by themselves in the same way as it now does wine. The dietary of every mess is not to contain either salads or vegetables which are eaten raw, such as radishes or artichokes. All inhabited places are to be kept in a proper state of cleanliness and special care is to be exercised in the

only be secured under various restrictions under the special Acts of that company and, of course, at very considerable cost. Under the yoke of these disadvantages several attempts were made to place the Newcastle company under statutory obligations to supply the Tynemouth borough, but the Newcastle company was joined by the corporations of Newcastle and Gateshead in active resistance to any such scheme. Two Glasgow Medical Practitioners Sued for £20,000.

It is with considerable interest that the medical profession in the West of Scotland has watched the progress in the Court of Session of an action brought against two Glasgow medical practitioners, and the verdict has been hailed with a certain amount of relief, although it is difficult to see how it could have been otherwise. The action was raised at the instance of a Clyde pilot who sued Dr. Marion Gilchrist, a practitioner in the West-end of Glasgow, and Mr. John Carswell, an expert in lunacy of the same city, for £10,000 each for alleged unprofessional conduct in granting certificates to the effect that the pursuer was of unsound mind and thereby causing his incarceration in Gartnavel Lunatic Asylum from September, 1903, to January, 1904. The pursuer's case was that the defenders acted negligently and unprofessionally and made no independent or adequate inquiry into the pursuer's statements or ascertained definitely the pursuer's mental condition and that they did not consult his own

cleaning of floors, which are to be brushed over with a 5 per cent. solution of chloride of lime, while the walls of rooms are to be whitewashed with lime-wash containing also chloride of lime. Men on leave are to be warned specially as to the danger of drinking town water and are also to be exhorted to avoid excess of any kind. Any man who appears to be ill, to be disinclined for work, or to have lost his appetite will be sent to the military hospital.

Death due to Cardiac Embolus while under an Anæsthetic.

At the meeting of the Society of Surgery held on Dec. 20th, 1905, M. Guinard showed the heart of a woman who was to have been operated upon for perimetritis, in which suppuration had occurred on the right side. The patient died quite suddenly on the table when she had just begun to take the chloroform. The apparatus used was Ricard's. Death was supposed to be due to the chloroform but a post-mortem examination revealed a large clot in the right ventricle, which clot was entangled in the chordæ tendinæ of the tricuspid valve. The origin of the clot was found to be in the hypogastric vein, just where it empties itself into the iliac vein. The clot had evidently been detached while the patient was being examined on the table or possibly in the pre-anæsthetic stage of excitement.

The Transmission of Contagious Diseases by School Books.

At the meeting of the Academy of Medicine held on Dec. 19th M. Josias read a paper founded on some inquiries made by M. Lop. This observer insisted upon the necessity for taking measures to prevent the transmission of infectious diseases by school books. There can be no doubt that scarlet fever is transmitted in this way and it is highly probable that tuberculosis, diphtheria, and other contagious diseases are so too. M. Lop proposes that at the end of each scholastic year books which are to be handed on to other scholars should be disinfected and all books in the possession of any child attacked by an infectious disease should also be disinfected. Exposure to high-pressure steam for 40 minutes is an excellent disinfectant but this method destroys bindings. The most practical method is that of Michel, which is based upon the use of the vapour of formic aldehyde.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Medical Examination of School Children.

THE report on the work of the medical officers of the Berlin municipal schools shows that, although these appointments are of comparatively recent creation, the duties to be performed have already become very extensive. These medical officers have to examine all the new pupils who enter the schools at the beginning of both the winter and the summer semesters, a task of magnitude, as each school district includes from seven to nine schools and the number of new pupils during the period under consideration was 34,562. Among these children 2927 were not admitted, some of the causes, together with the number of cases under each heading, being as follows: general debility, 1091; rachitis, 519; various mental defects, including idiocy, 300; scrofulosis, 184; nervous diseases, 81; and cardiac disease, 76. Of the other children 7041, or 20 per cent. of the total, suffered from chronic diseases which did not exclude them from the schools but, however, made a regular examination by the medical officers necessary. Among the backward and mentally defective children there were 801 for whom instruction in special classes was necessary, and of these 32 had to be afterwards transferred to asylums for idiots. The medical officers have also to deal with the general hygiene of their respective schools and the report gives their remarks on ventilation, heating, light, &c. On the subject of infectious diseases it is stated that many parents when their children suffer from infectious diseases intentionally notify the case to the school authorities as one of an ordinary character, the object of this being to save themselves trouble or the risk of injury to their business or the necessity of keeping the children a long time at home. If a medical man is not consulted the convalescent children return to school before they are free from infection, to the great danger of their class fellows. Concerning tuberculosis, the report states that in the majority of cases the parents are not aware that their

children are tuberculous on entering school and the discovery is first made by the school medical officer. The tuberculous children were examined at regular intervals and when necessity arose they were removed either to the seaside or to sanatoriums elsewhere. The number of tuberculous children is stated to be about 2000.

Sunday Rest for Medical Practitioners.

The so-called English Sunday—i.e., the closing of shops and offices all day on Sunday—is a relatively new institution in Germany and was legally enacted only about 15 years ago to the great satisfaction of all concerned. Recently some classes which do not come under the above law—pharmaceutical chemists, for instance—have taken measures by voluntary agreement to enjoy a more or less complete Sunday rest and the same movement has also found favour among the members of the medical profession. The question was recently discussed at a meeting of the Frankfurt Medical Society where Dr. Eiermann delivered an address on Sunday Rest for Medical Practitioners. He said that the great majority of general practitioners scarcely ever had an opportunity of taking a trip to the country with their families on Sundays and that if they did so there was always a possibility that a patient might require attendance during the temporary absence of his usual medical adviser and might subsequently not return to him. In order that the medical men might obtain this much-needed relaxation without inconveniencing the public Dr. Eiermann proposed that the city should be mapped out into 17 divisions corresponding to the police districts and that the medical men of each division should come to an arrangement whereby one of them in turn should remain at home on Sunday in readiness to attend urgent cases for the other practitioners. The names of the medical men on Sunday duty might be published every Saturday in the local newspapers and could be ascertained at the district police stations where the public would make inquiry in case of need. Moreover, one specialist in every branch for the whole town would be at home on Sundays. In order that the new system should work without prejudice to the medical profession it would be essential that the practitioners on Sunday duty should be under an obligation to give immediate notice to the usual medical attendant of the family to which he had been called and that he should absolutely refrain from any kind of after-treatment. The Frankfurt Medical Society unanimously agreed with these proposals and passed a resolution that the scheme for obtaining rest on Sunday should be introduced in Frankfurt from Jan. 1st, 1906. It is to be hoped that the medical men of other large towns will soon follow the example of the Frankfurt practitioners.

(FROM OUR OWN CORRESPONDENT.)

The Dispensaries in the Provinces.

THE General Sanitary Council of the Ottoman Empire, says the Turkish newspaper *İkdam*, published in Stamboul, is preparing a plan of regulations for the reorganisation of all the provincial dispensaries, the state of affairs of which is at present extremely unsatisfactory. Some regulations concerning the dispensaries and druggists' shops of the metropolis and surrounding districts are already in existence. They are, however, incomplete and lack that strict definiteness which is so absolutely necessary in the art of dispensing. Many localities in the provinces have no dispensaries at all. The way in which drugs are sold and administered there is a most deplorable one. All sorts of domestic remedies, very often of an injurious nature, are, of course, in great vogue. Very frequently old women play the rôle of a dispenser and of a medical adviser as well. Various amulets and talismans are supposed to possess great healing powers. Recitations from the Koran by a skilful "hodja" or "imam" in the presence of a bedridden patient are considered to be of much greater efficacy than any drug or any medical instruction, however dangerous the state of the diseased person may be. If the patient dies it is said to be due to an evil eye or to the influence of the "shitan" (devil). The few existing provincial dispensaries are in a state, as already indicated, which is far from satisfactory. In some it would be in vain to look

for a balance or any contrivance for measuring the exact dosage. The pharmacist simply trusts to the indications of his hand and eye. One can easily imagine the mischief that arises from such a mode of exercising the practice of dispensing. Frequently the district medical man asks in vain for the necessary drug. Frequently, also, the ingredients are so old as to have lost all their efficacy. The physicians have therefore very often to renounce prescribing the most indispensable ingredient and to adapt themselves as best they can to the scanty means at their disposal. The above-mentioned plan of regulations will try to remedy matters in a more or less energetic manner. The authorities will henceforward never allow anybody to open a dispensary unless he possesses sufficient means to furnish it with all the necessary requirements and to keep in stock the requisite amount of drugs. A sum of at least 100 Turkish liras (about £90 sterling) is being estimated by the General Sanitary Council as the lowest limit of means necessary to open a more or less respectably equipped dispensary. The municipal provincial authorities will also be instructed to make provisions for the opening of dispensaries in those localities where they do not now exist. Sanitary inspectors will visit twice yearly the provinces for the purpose of controlling the dispensaries and the dispensers. If the above plans are realised the public health of the Ottoman Empire will, of course, benefit very much indeed. I must, however, add that from a plan to its fulfilment there is always in Turkey a great, and very frequently insurmountable, distance.

The Expansion of the Italian Hospital.

Mr. Giapelli, the Italian Consul-General at Constantinople, has recently returned from Italy, where he occupied himself with a plan of building a new pavilion for tuberculous patients in connexion with the Italian Hospital at Tophané, a district of the metropolis adjoining the business quarter of Galata. The carefully elaborated designs of the projected pavilion have already been submitted to Mr. Speroni, a well-known architect from Milan, whose specialty is the building of hospitals. He proposes to make alterations in these designs and as soon as his own plans arrive here the erection of the pavilion will commence. The latter will be built in accordance with all the necessary requirements of modern hygiene and sanitation.

A New Turkish Hospital at Port Said.

The Ottoman Government intends to build a hospital for poor patients at Port Said. The site for this hospital has already been bought and orders have been given to prepare the necessary plans and designs. The Sultan takes a keen interest in its construction.

A New Veterinary Bacteriological Institute.

In view of the extension of the epizootic that is raging in the provinces of Trebizond, Castemouni, Aidin, Bronssa, Syria, Aleppo, and Beyrout the Ministry of Agriculture has asked the Sublime Porte for an authorisation to build in Constantinople a large veterinary bacteriological institute, as the existing laboratories are quite inadequate to meet the exigencies in furnishing serum in sufficient quantities to combat the outbreak.

A Strange "Remedy."

The inhabitants of Cassaba and Nif have recourse to a strange "remedy" for the epizootic raging in those places. The peasants there, to begin with, use every means possible at their disposal to prevent veterinary surgeons doing their work of prophylaxis and isolation. They oppose most energetically every mode of veterinary treatment and frequently insult and ill-treat the surgeon in the roughest manner. Their own domestic "remedy" for the prevention of contagion, a "remedy" in which they put absolute confidence, consists in the following. They kill a diseased animal and take out its liver and cut it into pieces. They then attach these latter with seven strings, all of a different colour, to the backs of the ears of the healthy animals which they henceforward consider to be safe from every contagion. Should an animal, however, die all the same the peasants attribute its death to the evil eye of the veterinary surgeon.

The First Snow.

After an exceptionally prolonged period of very mild weather we have got at last the first frost and the first snow. It is rare, however, for snow to last here. No sooner does it fall than it melts again. Severe winters are an exception at Constantinople.

Dec. 22nd, 1905.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

A Substantial Compliment.

IN order to show their appreciation of his labours in keeping the city free from yellow fever during the recent outbreak in the Southern States, a purse of \$10,000, collected by popular subscription, was recently presented to Dr. Heber Jones, president of the Memphis (Tennessee), board of health. Dr. Jones sacrificed all other interests in order to be able to give his full time to the problems of quarantine and sanitation, and the value of his efforts is shown by the fact that, although many towns not far distant suffered, Memphis remained free from the disease.

Prize for Essay on Epilepsy.

A prize of \$300 has been offered by the National Association for the Study of Epilepsy for the best essay dealing with the etiology of that disease. All essays must be in the hands of the examining committee by Sept. 1st, 1906, and the award will be made in the following November. Physicians in any country may compete for the prize. Full information regarding the conditions of the award may be obtained from the president of the association, Dr. W. P. Spratling, superintendent of the Craig Colony for Epileptics, Sonyea, Livingston County, New York.

Football Accidents.

A wave of popular indignation has been sweeping over the entire country on account of the constantly growing annual record of serious and even fatal football casualties. In recent years the record of fatalities has increased at a rate that does not seem explicable merely on the ground of more general interest in the game, and for this season it is estimated that over a score of deaths and at least 150 grave injuries occurred. It is usually the comparatively untrained and immature players of undergraduate elevens who suffer, but many seasoned members of collegiate teams are also included in the list. Four deaths were due to body blows giving rise to internal injuries, six were ascribed to cerebral concussion, and three to spinal injuries. Blood poisoning and other injuries are responsible for the remaining fatal cases. The list of the seriously hurt includes many fractures of the limbs, ribs, and collar bone, injuries of the head and spine, and concussion of the brain. It is supposed that if accurate statistics could be compiled the total number of accidents of a more or less serious character would exceed 1000. This terrifying record is no doubt largely due to the fact that the rules of the game have been gradually so changed that as it is now played in this country it has but little resemblance to its English prototype. Open play has been reduced to a minimum and the mass formations in vogue not only of themselves render fatalities common but also afford undesirable opportunities for undetected fouls and brutality which are unfortunately far too common. In consequence of the popular disapproval of the present game the authorities of the more prominent colleges and universities are taking radical steps to purge the rules of their objectionable features, even President Roosevelt going so far as to take a hand in the matter. At Columbia University football has been abolished absolutely.

Medical Examinations in New York State.

A conference was recently held in Albany to consider the advisability of substituting a single State medical board for the three now representing respectively the regular, homœopathic, and eclectic schools of medicine. The representatives of the various State medical societies and State medical boards, after considerable discussion, finally decided to retain for the present the three boards of medical examiners now existing. The matter of arranging the academic and professional courses of instruction so as to render it possible to obtain the degrees of B.A. and M.D. in seven instead of eight years has been under consideration for some time and steps have already been taken in this direction. A committee was appointed at the present conference for the purpose of preparing the outline for a course of study to be introduced into the junior and senior years of the colleges, which should be satisfactory to the medical schools of the State and be accepted by them in lieu of their first year's work.

Dec. 27th, 1905.

cleaning of floors, which are to be brushed over with a 5 per cent. solution of chloride of lime, while the walls of rooms are to be whitewashed with lime-wash containing also chloride of lime. Men on leave are to be warned specially as to the danger of drinking town water and are also to be exhorted to avoid excess of any kind. Any man who appears to be ill, to be disinclined for work, or to have lost his appetite will be sent to the military hospital.

Death due to Cardiac Embolus while under an Anæsthetic.

At the meeting of the Society of Surgery held on Dec. 20th, 1905, M. Guinard showed the heart of a woman who was to have been operated upon for perimetritis, in which suppuration had occurred on the right side. The patient died quite suddenly on the table when she had just begun to take the chloroform. The apparatus used was Ricard's. Death was supposed to be due to the chloroform but a post-mortem examination revealed a large clot in the right ventricle, which clot was entangled in the chordæ tendinæ of the tricuspid valve. The origin of the clot was found to be in the hypogastric vein, just where it empties itself into the iliac vein. The clot had evidently been detached while the patient was being examined on the table or possibly in the pre-anæsthetic stage of excitement.

The Transmission of Contagious Diseases by School Books.

At the meeting of the Academy of Medicine held on Dec. 19th M. Jostias read a paper founded on some inquiries made by M. Lop. This observer insisted upon the necessity for taking measures to prevent the transmission of infectious diseases by school books. There can be no doubt that scarlet fever is transmitted in this way and it is highly probable that tuberculosis, diphtheria, and other contagious diseases are so too. M. Lop proposes that at the end of each scholastic year books which are to be handed on to other scholars should be disinfected and all books in the possession of any child attacked by an infectious disease should also be disinfected. Exposure to high-pressure steam for 40 minutes is an excellent disinfectant but this method destroys bindings. The most practical method is that of Michel, which is based upon the use of the vapour of formic aldehyde.

The Dispensaries in the Provinces.

THE General Sanitary Council of the Ottoman Empire, says the Turkish newspaper *İkdam*, published in Stamboul, is preparing a plan of regulations for the reorganisation of all the provincial dispensaries, the state of affairs of which is at present extremely unsatisfactory. Some regulations concerning the dispensaries and druggists' shops of the metropolis and surrounding districts are already in existence. They are, however, incomplete and lack that strict definiteness which is so absolutely necessary in the art of dispensing. Many localities in the provinces have no dispensaries at all. The way in which drugs are sold and administered there is a most deplorable one. All sorts of domestic remedies, very often of an injurious nature, are, of course, in great vogue. Very frequently old women play the rôle of a dispenser and of a medical adviser as well. Various amulets and talismans are supposed to possess great healing powers. Recitations from the Koran by a skilful "hodja" or "imam" in the presence of a bedridden patient are considered to be of much greater efficacy than any drug or any medical instruction, however dangerous the state of the diseased person may be. If the patient dies it is said to be due to an evil eye or to the influence of the "shitan" (devil). The few existing provincial dispensaries are in a state, as already indicated, which is far from satisfactory. In some it would be in vain to look

£100, and Fishmongers' Company, 25 guineas—Lord Ludlow, treasurer of St Bartholomew's Hospital, has received £100 from "A Friend" for the general funds of the hospital—By the will of Mr. Lewis James Seargeant of Tunbridge Wells £1000 are bequeathed to King Edward's Hospital Fund for London

ACTION FOR THE RECOVERY OF MEDICAL FEES.—At the Bristol county court on Dec 22nd, 1905, Mr. C. C. Pratt, surgeon, of Clifton, claimed £47 from a gentleman for medical attendance upon his mother-in-law. Evidence showed that the defendant and his wife placed the patient in charge of a lodging house keeper in Clifton, with instructions to procure for the old lady all that was necessary, including medical attendance. The defendant had paid Mr. Pratt a previous account for his attendance upon the patient. Judgment was given for the plaintiff.

THE ROYAL WEST OF ENGLAND SANATORIUM, WESTON-SUPER-MARE.—The Royal West of England Sanatorium at Weston-super-Mare is much appreciated by convalescent patients, for during the past year 2470 cases have been admitted, the daily average number of patients being nearly 200. It has recently been decided to build an annexe to the institution and this will be used by the nursing staff, and the wards which they at present occupy will give more accommodation to patients. It will also be utilised for any infectious case should an outbreak arise in the sanatorium. The committee has received £900 from a legacy which will be devoted towards the building and it is hoped that the additional sum required will be shortly forthcoming.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced—Dr. E. von Kusy, director of the sanitary department of the Austrian Ministry of the Interior.—Dr. Carlo Rosanelli, formerly extraordinary professor of general pathology in the University of Padua.—Dr. De Villo W. Harrington, professor of urinary diseases in the University of Buffalo.—Dr. Domenico Chiara, formerly professor of midwifery and gynecology in the Florence Medical School.—Dr. P. Abramichoff, *privat dozent* of dermatology and syphilography in the St Petersburg Military Medical Academy.—Dr. Cornelis Laendert van der Burg, a well known authority on the medico-geographical pathology of the Dutch East Indies. He was 65 years of age.—Dr. Sousa Reisfois, professor of medicine in the University of Coimbra.—Dr. Ambrose L. Ranney, professor of neurology and mental diseases in the University of Vermont, Burlington.—Dr. Hans Schmaus, extraordinary professor of pathological anatomy in the University of Munich, at the age of 43 years.—Dr. J. M. Holloway, formerly professor of clinical surgery in the Kentucky School of Medicine.—Dr. Hermann Rahl Rückhard, *privat dozent* of anatomy in the University of Berlin. He received the Iron Cross for his services during the Franco-German war. He was granted the title of professor in 1884 and was for some years a member of the military examination commission. His published works deal with a variety of subjects, especially military hygiene and malingering.—Dr. André Thourvenet, formerly professor of physiology in the Idmoges Medical School.—Dr. F. Hesch, extraordinary professor of ophthalmology in the University of Basle.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

ANDERSON, R. W., M.R.C.S., L.R.C.P. Lond., has been appointed Medical Practitioner under the Workers Compensation Act for Christchurch, New Zealand.
ANGELL, W. T., M.R.C.S. Eng., has been appointed Medical Officer to attend to the Destitute Persons and Aborigines within the District of Talinga, South Australia.
BARNARD, CHARLES EDWARD, M.D., Ch.M. Edin., has been appointed Officer of Health for the Shire of Creswick, Victoria, Australia.
BLIND, RICHARD KINGSTON, L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for Arapiles Shire, Victoria, Australia.
BOYLE, H. EDWARD G., M.R.C.S., L.R.C.P. Lond., has been appointed Honorary Anesthetist to the Paddington Green Children's Hospital.
CAMPELL, DONALD ALBERT, M.B. Melb., has been appointed Senior Medical Officer to the Hospital for the Insane, Larra Bend, Victoria, Australia.

DICKSON, FRANCIS HENRY, M.B., Ch.B. Edin., has been appointed Junior Assistant House Surgeon at the Stockport Infirmary.
GARRY, J. P., L.R.C.P. Edin., M.R.C.S., has been appointed District Medical Officer of the King's Norton Union.
HILL, ARTHUR MACHEN, M.B., Ch.B. Melb., has been appointed Medical Officer for Newstead Shire, Victoria, Australia, temporarily.
HOLLOWAY, JOSEPH THOMAS, M.B. Melb., has been appointed Medical Superintendent of the Ballarat Hospital for the Insane, Victoria, Australia, *pro tem*.
JAMES, WALTER TIMOTHY, M.B., Ch.B. Edin., has been appointed a District Medical Officer for the Aberavon (Cardiganshire) Union.
LIDDLER, PERCY HENRY, M.B., Ch.B. Melb., has been appointed Medical Officer for the Borough of Dariesford, Victoria, Australia.
OLLIPHANT, ROBERT, M.B., Ch.B. Vict., has been appointed Assistant House Surgeon to the Liverpool Infirmary for Children.
PHILLIPS, ALBERT JOHN WILLIAM, M.B., Ch.B. Melb., has been appointed Medical Superintendent to the Hospital for the Insane, Seeworth, Victoria, Australia.
SMITH, H. WATSON, M.B., Ch.B. Aberd., has been appointed Second Assistant Medical Officer to the Durham County Asylum, Winterton Ferryhill.
STEWART, J. M. I., M.B., Ch.M. Glasg., has been appointed Gynecologist for Out-patients at the Perth Hospital, West Australia.
THOMPSON, GEORGE WILLIAM, M.B. Edin., F.R.C.S. Eng., has been appointed Ophthalmic Surgeon in charge of Out-patients at the French Hospital Shaftesbury Avenue.
WALTON, GEORGE ERNEST, B.A. Cantab., M.D., D.S. Lond., F.R.C.S. Eng., has been appointed Assistant Surgeon to the Hospital for Sick Children Great Ormond-street.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index)

BIRMINGHAM AND MIDLAND EAR AND THROAT HOSPITAL, Edmund street.—House Surgeon. Salary at rate of £70 per annum.
BIRMINGHAM, UNIVERSITY OF.—Demonstratorship in Anatomy. Stipend £175 per annum.
BRISTOL ROYAL INFIRMARY.—Pathologist, Bacteriologist, and Director of Clinical Laboratories. Salary £250 per annum.
BURNLEY, CORRYT BOBOTHOM.—Medical Officer of Health. Salary £500 per annum.
CHESTER GENERAL INFIRMARY.—House Surgeon. Salary £100 per annum, with residence and maintenance.
DERBYSHIRE ROYAL INFIRMARY.—Two House Surgeons, one House Physician, and one Assistant House Surgeon. Salary of three former £100 per annum, with apartments, board &c., of latter at rate of £60 per annum with apartments, board, &c.
GREAT LARMOUTH HOSPITAL.—House Surgeon. Salary £93 per annum, with board, lodging, and washing.
HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Resident House Physicians.
MIDDELSBROUGH, NORTH RIDING INFIRMARY.—Assistant House Surgeon, unmarried. Salary £75 per annum, with residence, board, and washing.
NAPTHAL, NEAR ST ALBANS, HERTS, MIDDLESEX COUNTY ASYLUM.—Assistant Medical Officer. Salary £150 per annum, with board, lodging, washing, and attendance.
NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen's square, Bloomsbury, W.C.—Resident Medical Officer. Salary £100 per annum, with board and residence.
NORTHAMPTON GENERAL HOSPITAL.—House Surgeon, unmarried. Salary £90 per annum, with apartments, board, attendance, and washing.
ROYAL FREE HOSPITAL, Gray's Inn road, W.C.—Medical Registrar, also a Surgical Registrar (females).
SALFORD ROYAL HOSPITAL.—Honorary Assistant Surgeon.
UNIVERSITY OF LONDON.—Examiners. One each in Medicine, in Surgery, and in Pathology.
VICTORIA HOSPITAL FOR CHILDREN, Tite-street, Chelsea, S.W.—House Surgeon for six months. Honorarium of £25, with board and lodging.
YORK DISPENSARY.—Resident Medical Officer, unmarried. Salary £120 a year, with board, lodging and attendance.

Births, Marriages, and Deaths.

BIRTHS.

BEATTON.—At The Cliffe, Bradford, on the 2nd January, 1906, the wife of Dr. Gilbert T. Beatton, of a daughter.
FARNFIELD.—On Dec. 25th, 1905 at Mere, Wilts the wife of William Walter Farnfield M.R.C.S. Eng., L.R.C.P. Lond. of a daughter.
FORBES.—On Dec. 27th 1905, at Oakwood-court, Kensington, W., the wife of J. Graham Forbes M.D. M.R.C.P., of a daughter.
SOPER.—On Dec. 29th 1905, at Clapham road S.W., the wife of Bertram Soper, L.R.C.P. (nee Frances Ash), of a son.

DEATHS.

DANIEL.—On Dec 30th 1905 at the Silver Birchess Eprom, William Clement Daniel, M.D., M.R.C.S., L.S.A., aged 60 years.
GRAY.—On 23th December at 92, Anerley Park, London S.E., Thomas Gray, M.R.C.S. Eng., and L.S.A. (formerly of 12, Montague place, Poplar, E.) in his 89th year.
GREENER.—On Dec. 25th, 1905, at Fallowden, Cathedral road, Cardiff, Michael Hindmarsh Greener, M.B., C.M.

A.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At a Congregation on Dec. 14th, 1905, the following degrees were conferred:—

M.B.—A. W. Wakefield, Trinity; S. Borraddell-Smith, St. John's; W. R. Higgins, Calus; and C. F. Hardie, Queens'.

B.C.—A. W. Wakefield, Trinity; and S. Borraddell-Smith, St. John's.

At examinations for medical and surgical degrees held in Michaelmas term the following candidates were successful:—

FIRST EXAMINATION.

Part I., Chemistry and Physics.—C. K. Bancroft and H. G. Baynes, Trinity; F. S. Bedale, Clare; C. H. B. Booth, King's; A. W. Bourne, Downing; H. H. Brown, Calus; E. G. S. Cane, Jesus; R. G. Cant, B.A., King's; F. G. Chandler, Jesus; K. J. A. Davis, B.A., King's; H. T. Depree, Clare; C. Edo, King's; W. G. Emmett, Calus; A. G. Evans, Trinity; A. E. Evans, St. John's; G. W. B. Garrett, Calus; E. M. Grace, Christ's; L. S. M. Habich, St. John's; B. C. Haller, B.A., Trinity; J. B. Hance, Christ's; J. R. Henth, Trinity; A. E. Herman, King's; L. C. D. Irvine, Emmanuel; G. James, St. John's; A. O. Johnson, Downing; G. G. Johnstone, King's; T. H. Just, Trinity; H. D. Lander, Calus; G. H. S. Lettsworth, Pembroke; D. N. Macleod, Calus; J. R. Marrack, St. John's; W. G. Marsden, Emmanuel; G. W. Morrice and R. S. Morhead, Trinity; G. A. Morton, Queens'; B. A. Payne, Pembroke; H. B. Pope, Calus; E. Rayner, Pembroke; K. C. Rayner, Calus; A. H. Richardson, St. John's; W. D. Ross and S. H. Rouquette, King's; A. O. Roxburgh, Trinity; W. A. Russell, Emmanuel; H. B. G. Russell, Sidney Sussex; H. W. Scott, Clare; G. B. Sutton, Pembroke; R. H. Vicary, G. T. C. Watt, and J. B. A. Wymore, Calus; and C. R. Wright, Christ's.

Part II., Elementary Biology.—F. Ballard, Catharine; C. K. Bancroft, Trinity; F. S. Bedale, Clare; A. W. Bourne, Downing; E. G. S. Cane, Jesus; R. G. Cant, B.A., King's; F. G. Chandler, Jesus; K. J. A. Davis, B.A., King's; H. T. Depree, Clare; W. O. Emmett, Calus; A. G. Evans, Trinity; G. W. B. Garrett, Calus; A. Griffith-Williams and B. C. Haller, B.A., Trinity; T. L. Hardy, H. Selwyn; J. Harrison, B.A., Christ's; L. C. D. Irvine, Emmanuel; A. C. Johnson, Downing; G. G. Johnstone, King's; W. H. Jones, B.A., Christ's; T. H. Just, C. O. Kerby, and M. MacLaren, Trinity; W. G. Marsden, Emmanuel; O. de M. Marsh, Pembroke; G. A. Morton, Queens'; F. A. Powell, Trinity; E. Rayner, Pembroke; E. C. Rayner, Calus; W. J. Richardson, H. Selwyn; F. E. W. Rogers, Emmanuel; W. D. Ross and S. H. Rouquette, King's; A. C. Roxburgh, Trinity; W. A. Russell and C. M. Ryley, Emmanuel; L. W. K. Scargill, M.A., Trinity Hall; H. C. S. Starkey, Downing; J. L. M. Symms, Calus; and H. A. Williams, Emmanuel.

SECOND EXAMINATION.

Human Anatomy and Physiology.—J. W. Adams and G. E. Alderson, Calus; D. Allan, B.A., St. John's; F. R. Armitage, B.A., Pembroke; C. O. H. Bluns, Calus; H. Bowring, B.A., King's; W. Boye-Stones, B.A., Calus; R. D. D.-D. Brownson, B.A., St. John's; H. T. H. Butt, B.A., Christ's; F. G. Caley, B.A., Pembroke; W. N. Child, B.A., Christ's; A. J. Clark, King's; C. N. Cond, B.A., St. John's; M. Donaldson, B.A., Trinity; H. B. Elton, B.A., Calus; R. Fisher, Sidney Sussex; H. G. Fresh, B.A., St. John's; H. D. Gillies, B.A., Calus; A. H. Habgood, B.A., Jesus; W. Harman, B.A., Trinity; E. H. V. Hodge, B.A., Clare; W. C. Hodges, B.A., Trinity Hall; A. N. Hodges, Queens'; C. O. Holman, Calus; B. Hughes, B.A., H. Selwyn; H. D. Humphrys, B.A., E. M. Lauderdale, B.A., and R. J. B. Loney, Calus; G. K. McKerrrow, B.A., Clare; R. H. Mawhood, B.A., Trinity; R. M. Moore, B.A., St. John's; H. M. D. Nicoll and A. E. Rayner, B.A., Calus; H. G. Rice, St. John's; F. A. Roper, B.A., and E. N. Russell, Trinity; F. S. Seales, B.A., Jesus; A. L. H. Smith and H. C. Snell, B.A., Calus; H. S. S. Stiven, B.A., Trinity; L. B. C. Trotter, B.A., Clare; R. M. Vick, B.A., Jesus; C. St. A. Viriau, B.A., Calus; J. Walker, B.A., and W. E. Wallis, B.A., Clare; H. B. Wilson, B.A., Pembroke; P. F. Wilson, B.A., Calus; W. B. Wood, B.A., Jesus; S. Wood, B.A., Christ's; and C. S. E. Wright, B.A., Emmanuel.

THIRD EXAMINATION.

Part I., Pharmacology and General Pathology.—A. Abrahams, Emmanuel; R. R. Armstrong, Trinity; B. T. Ashby, B.A., Emmanuel; A. S. B. Bankart, B.A., Trinity; B. P. Campbell, B.A., Clare; J. R. O. Canney, B.A., Christ's; W. J. Carr, B.A., Trinity; A. E. A. Carver, B.A., and S. P. Chan, Calus; S. Churchill, B.A., and F. Clayton, B.A., Trinity; R. Cox, B.A., Calus; A. H. Crook, B.A., Christ's; R. Davies Colley, B.A., Emmanuel; H. E. T. Davies, B.A., St. John's; B. Day, B.A., Calus; A. T. Densham, B.A., St. John's; H. Dimock, B.A., Sidney Sussex; G. H. Dunn, B.A., Pembroke; H. B. Ellison, B.A., Calus; D. Emblesdon, B.A., Christ's; M. F. Emrys-Jones, B.A., Calus; N. M. Ferguson, B.A., Magdalen; G. W. Goodhart, B.A., Trinity; W. H. Grandage, B.A., Clare; F. W. Griffin, B.A., King's; R. E. V. Hale, B.A., Calus; A. Hamilton, B.A., Christ's; O. Heath, B.A., Trinity; G. Hoffmann, B.A., Calus; W. M. Jeffcoy, B.A., Trinity; N. W. J. Jenkin, B.A., Christ's; W. S. Leicester, B.A., Emmanuel; J. T. Macnab, B.A., Christ's; J. Mellanby, B.A., Calus; E. E. Paget-Orton, B.A., Trinity; H. B. Owen, B.A., Calus; E. F. Priestley, B.A., Trinity; W. C. Parkin, B.A., Emmanuel; H. Parsons, B.A., B. C. Priest, B.A., and R. F. Priestley, B.A., and Calus; C. L. Redman, B.A., Pembroke; L. W. Sharp, B.A., and O. R. Smale, B.A., Calus; E. R. Stone, B.A., Emmanuel; A. C. Sturdy, Pembroke; R. Swanson, B.A., Calus; H. H. Taylor, B.A., Pembroke; F. D. Treves, B.A., Calus; R. W. S. Waller, B.A., Trinity; and C. E. Whitehead, B.A., Calus.

Part II., Surgery, Midwifery, and Medicine.—The following have now sat the examination in all three sections: C. Akerman, B.A., Calus; E. D. Anderson, B.A., Pembroke; A. D. Brunt, B.A., Trinity; M. A. Cassidy, B.A., Clare; G. H. U. Corbett, B.A., King's; G. L. Cox, B.A., Christ's; F. D. Crew, B.A., Emmanuel; L. G. Davies, B.A., Trinity; A. H. Falkner, B.A., Peterhouse; J. N. F. Ferguson, B.A., and S. Gooding, M.A., St. John's.

H. T. Gray, B.A., Trinity; S. L. Harke, B.A., Pembroke; W. H. Hastings, B.A., and S. A. Henry, B.A., Trinity; F. S. Hewitt, B.A., Calus; H. F. V. Hodge, B.A., Emmanuel; A. B. Howitt, B.A., Clare; C. L. Isaac, B.A., and F. A. G. Jeans, M.A., St. John's; W. D. Keyworth, B.A., H. Selwyn; J. O. Leaton-Roberts, B.A., Clare; C. M. Le Brocq, B.A., Pembroke; W. B. Lee, B.A., Trinity; F. F. Leighton, B.A., St. John's; C. Lillingston, B.A., Pembroke; G. H. K. Macalister, B.A., St. John's; A. D. Miller, B.A., Trinity; W. P. Morgan, M.A., Clare; T. M. A. Nasty, M.A., and W. H. Newton, B.A., Emmanuel; G. W. de P. Nicholson, M.A., Jesus; W. H. Orton, B.A., Trinity; H. B. Owen, B.A., Calus; O. H. W. Page, M.A., Corpus Christi; C. T. Scott, M.A., Sidney Sussex; F. Shingleton-Smith, B.A., King's; G. C. E. Simpson, B.A., St. John's; J. M. Smith, B.A., Christ's; and R. S. Taylor, B.A., and W. P. Williams, B.A., Downing.

UNIVERSITY OF OXFORD.—At the Preliminary Examinations in Science the following candidates satisfied the examiners:—

Mechanics and Physics.—A. Booth, G. O. Boyd, M. de G. Boyd, C. E. N. Bromhead, A. J. B. Carrington, G. C. Clarence, R. E. Oullis, R. R. Enfield, C. R. Featherstone, R. J. Fletcher, P. L. Gibson, N. F. Hallows, A. H. Harries, T. K. Heaton, J. K. Hepburn, G. R. Hookham, J. P. Hucklebridge, J. M. Mason, M. Odling, W. J. Pearson, J. B. Reynish, I. P. Venner, V. S. von Dembski, and D. F. Wütsch.

Physics.—C. W. Armstrong, A. D. S. Arundel, T. B. Batefelor, J. L. Birley, R. B. O. Briscoe, P. R. Fairclough, H. J. H. Foreshe, C. L. Garton, M. R. Lawrence, S. F. Moore, and H. G. Morris.

Chemistry.—H. M. Bond, L. C. Boyd, C. E. N. Bromhead, C. D. Budd, A. M. Carr-Saunders, C. F. Cranswick, H. E. Cullis, V. G. Dearden, G. O. Dixon, R. R. Enfield, C. R. Featherstone, H. J. L. Foreshe, A. D. Gardner, P. L. Gibson, H. A. Gilbert, N. F. Hallows, C. H. L. Harper, A. H. Harries, T. K. Heaton, S. Hibbert, J. P. Hucklebridge, M. B. Lawrence, D. P. McDonald, L. K. Morrison, M. Odling, A. P. Orde-Ward, R. C. Oance, C. B. Pearson, J. P. Purnell-Edwards, J. B. Reynish, J. Russell, R. B. Simpson, E. A. Smythies, W. H. Thornton, I. P. Venner, V. S. von Dembski, J. T. Willis, C. O. Wilson, and D. F. Wütsch.

Botany.—T. B. Batefelor, A. R. Chavasse, A. W. Donaldson, H. G. Farmer, J. K. Hepburn, L. E. Meinertzhagen, P. le F. Norgis, H. M. Pope, E. A. Smythies, and A. Staeger.

FOREIGN UNIVERSITY INTELLIGENCE.

Algeria: Dr. Cange has been promoted to the chair of Clinical Ophthalmology. **Baltimore (Johns Hopkins University):** Dr. Charles H. Bunting has been appointed Assistant Professor of Pathological Anatomy; Dr. Thomas R. Boggs, Assistant Professor of Medicine; and Dr. Richard H. Folliis, Assistant Professor of Surgery. **Breslau:** Dr. Rudolf Stich has been recognised as *privat-docent* of Surgery. **Cincinnati (Miami Medical College):** Dr. O. P. Holt, Professor of Physiology, has been appointed to the chair of Pathological Anatomy. Dr. Robert Ingram has been appointed Assistant Professor of Materia Medica. **Copenhagen:** Dr. N. P. Schierbeck has been appointed *privat-docent* of Hygiene and Director of the Hygienic Laboratory. Dr. A. Heiblad has been recognised as *privat-docent* of Surgery. **Cracow:** Dr. Vincenz Lepkowski has been promoted to an Extraordinary Professorship of Odontology. **Innsbruck:** Dr. Paul Rasch has been recognised as *privat-docent* of Skin Diseases. **Lemberg:** Dr. Josef Markowski has been recognised as *privat-docent* of Anatomy. **Louisville:** Dr. John G. Cecil, Professor of Therapeutics, has been appointed Professor of Clinical Medicine in succession to the late Dr. J. A. Quackler. **Michigan (Ann Arbor University):** Dr. Albert M. Barrett has been appointed Assistant Professor of Neurology. **Philadelphia (University of Pennsylvania):** Dr. W. H. F. Addison of Toronto has been appointed Lecturer on Histology. **St. Petersburg (Female Medical Institute):** Dr. K. Susloff has been appointed Extraordinary Professor of Operative Medicine. **Vienna:** Dr. Arthur Schatzenfroh has been promoted to an Ordinary Professorship of Hygiene.

DEATH FROM ANTHRAX.—An inquest was held at Penryn, Cornwall, on Dec. 22nd, 1905, respecting the death of a labourer, aged 31 years. It was stated that the deceased received a scratch on the hand while unloading bones. Medical evidence showed that death was due to anthrax and the jury returned a verdict to that effect.

DONATIONS AND BEQUESTS.—At the opening of the Hampstead General Hospital recently the President, Sir H. Harben, announced that an anonymous donor had offered to give £20,000 on condition that £5000 were subscribed within a very short time. By the will of Miss Elizabeth Flint of Leek, Staffordshire, £1000 are bequeathed to the Leek Memorial Cottage Hospital, £400 to the Cruso Memorial Nursing Institution, £500 for the Royal Medical Benevolent College, £500 to the Devonshire Hospital and Bath Charity at Buxton, and £500 to the North Stafford Infirmary. Mrs. Umfreville Pickering has given £1050 to the West London Hospital, Hammersmith-road, W. The London Lock Hospital and Rescue Home has received the following donations: Goldsmiths' Company, £100; Mercers' Company,

£100; and Fishmongers' Company, 25 guineas.—Lord Ludlow, treasurer of St. Bartholomew's Hospital, has received £100 from "A Friend" for the general funds of the hospital.—By the will of Mr. Lewis James Sargeant of Tunbridge Wells £1000 are bequeathed to King Edward's Hospital Fund for London.

ACTION FOR THE RECOVERY OF MEDICAL FEES.—At the Bristol county court on Dec. 22nd, 1905, Mr. C. C. Pratt, surgeon, of Clifton, claimed £47 from a gentleman for medical attendance upon his mother-in-law. Evidence showed that the defendant and his wife placed the patient in charge of a lodging-house keeper in Clifton, with instructions to procure for the old lady all that was necessary, including medical attendance. The defendant had paid Mr. Pratt a previous account for his attendance upon the patient. Judgment was given for the plaintiff.

THE ROYAL WEST OF ENGLAND SANATORIUM, WESTON-SUPER-MARE.—The Royal West of England Sanatorium at Weston-super-Mare is much appreciated by convalescent patients, for during the past year 2470 cases have been admitted, the daily average number of patients being nearly 200. It has recently been decided to build an annex to the institution and this will be used by the nursing staff, and the wards which they at present occupy will give more accommodation to patients. It will also be utilised for any infectious case should an outbreak arise in the sanatorium. The committee has received £900 from a legacy which will be devoted towards the building and it is hoped that the additional sum required will be shortly forthcoming.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. E. von Kusy, director of the sanitary department of the Austrian Ministry of the Interior.—Dr. Carlo Rosanelli, formerly extraordinary professor of general pathology in the University of Padua.—Dr. De Villo W. Harrington, professor of urinary diseases in the University of Buffalo.—Dr. Domenico Chiara, formerly professor of midwifery and gynaecology in the Florence Medical School.—Dr. P. Abramichoff, *privat-docent* of dermatology and syphilography in the St. Petersburg Military Medical Academy.—Dr. Cornelis Laender van der Barg, a well-known authority on the medico-geographical pathology of the Dutch East Indies. He was 65 years of age.—Dr. Sousa Refoios, professor of medicine in the University of Coimbra.—Dr. Ambrose L. Ranney, professor of neurology and mental diseases in the University of Vermont, Burlington.—Dr. Hans Schmaus, extraordinary professor of pathological anatomy in the University of Munich, at the age of 43 years.—Dr. J. M. Holloway, formerly professor of clinical surgery in the Kentucky School of Medicine.—Dr. Hermann Rahl-Rückhard, *privat-docent* of anatomy in the University of Berlin. He received the Iron Cross for his services during the Franco-German war. He was granted the title of professor in 1884 and was for some years a member of the military examination commission. His published works deal with a variety of subjects, especially military hygiene and malingering.—Dr. André Thouvenet, formerly professor of physiology in the Limoges Medical School.—Dr. F. Hesch, extraordinary professor of ophthalmology in the University of Basle.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

ANDERSON, R. W., M.B.O.S., L.R.C.P. Lond., has been appointed Medical Practitioner under the Workers' Compensation Act for Chatham, New Zealand.
ASGORE, W. T., M.B.O.S. Eng., has been appointed Medical Officer to attend to the Destitute Persons and Aborigines within the District of Talinga, South Australia.
BARNARD, CHARLES EDWARD, M.D., Ch.M. Edin., has been appointed Officer of Health for the Shire of Greendale, Victoria, Australia.
BIRD, ROBERT EDWINSON, L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for Arapiles Shire, Victoria, Australia.
BOYLE, H. EDWARD G., M.R.C.S., L.R.C.P. Lond., has been appointed Honorary Anaesthetist to the Paddington Green Children's Hospital.
CAMPBELL, DONALD ALBERT, M.B. Melb., has been appointed Senior Medical Officer to the Hospital for the Insane, Yarra Bend, Victoria, Australia.

DICKSON, FRANCIS HENRY, M.B., Ch.B. Edin., has been appointed Junior Assistant House Surgeon at the Stockport Infirmary.
GAUNT, J. P., L.R.C.P. Edin., M.R.C.S., has been appointed District Medical Officer of the King's Norton Union.
HILL, ARTHUR MACHEN, M.B., Ch.B. Melb., has been appointed Medical Officer for Newstead Shire, Victoria, Australia, temporarily.
HOLLON, JOSEPH THOMAS, M.B. Melb., has been appointed Medical Superintendent of the Ballarat Hospital for the Insane, Victoria, Australia, pro tem.
JAMES, WALTER TIMOTHY, M.B., Ch.B. Edin., has been appointed a District Medical Officer for the Aberystwyth (Cardiganshire) Union.
LIDDLE, PERCY HERBERT, M.B., Ch.B. Melb., has been appointed Medical Officer for the Borough of Daylesford, Victoria, Australia.
OLIVERSHAW, ROBERT, M.B., Ch.B. Vict., has been appointed Assistant House Surgeon to the Liverpool Infirmary for Children.
PHILIPOTT, ALBERT JOHN WILLIAM, M.B., Ch.B. Melb., has been appointed Medical Superintendent to the Hospital for the Insane, Beechworth, Victoria, Australia.
SMITH, H. WATSON, M.B., Ch.B. Aberd., has been appointed Second Assistant Medical Officer to the Durham County Asylum, Winterton, Ferryhill.
STEWART, J. M. T., M.B., Ch.M. Glasg., has been appointed Gynaecologist for Out-patients at the Perth Hospital, West Australia.
THOMPSON, GEORGE WILLIAM, M.B. Edin., F.R.C.S. Eng., has been appointed Ophthalmic Surgeon in charge of Out-patients at the French Hospital, Shaftesbury-avenue.
WALCH, GEORGE ERNEST, B.A. Cantab., M.D., B.S. Lond., F.R.C.S. Eng., has been appointed Assistant Surgeon to the Hospital for Sick Children, Great Ormond-street.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BIRMINGHAM AND MIDLAND EAR AND THROAT HOSPITAL, Edmund-street.—House Surgeon. Salary at rate of £10 per annum.
BIRMINGHAM, UNIVERSITY OF.—Demonstratorship in Anatomy. Stipend £75 per annum.
BRISTOL ROYAL INFIRMARY.—Pathologist, Bacteriologist, and Director of Clinical Laboratories. Salary £250 per annum.
BURNLEY, COUNTY BOROUGH OF.—Medical Officer of Health. Salary £300 per annum.
CHESTER GENERAL INFIRMARY.—House Surgeon. Salary £100 per annum, with residence and maintenance.
DERBYSHIRE ROYAL INFIRMARY.—Two House Surgeons, one House Physician, and one Assistant House Surgeon. Salary of three former £100 per annum, with apartments, board, &c.; of latter at rate of £60 per annum, with apartments, board, &c.
GREAT YARMOUTH HOSPITAL.—House Surgeon. Salary £90 per annum, with board, lodging, and washing.
HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Resident House Physician.
MIDDLESEXBOURGH, NORTH RIDING INFIRMARY.—Assistant House Surgeon, unmarried. Salary £75 per annum, with residence, board, and washing.
NAPSLEY, NEAR ST. ALBAN'S, HERTS, MIDDLESEX COUNTY ASYLUM.—Assistant Medical Officer. Salary £150 per annum, with board, lodging, washing, and attendance.
NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.—Resident Medical Officer. Salary £100 per annum, with board and residence.
NORTHAMPTON GENERAL HOSPITAL.—House Surgeon, unmarried. Salary £90 per annum, with apartments, board, attendance, and washing.
ROYAL FREE HOSPITAL, Gray's Inn-road, W.C.—Medical Registrar; also a Surgical Registrar (females).
SALFORD ROYAL HOSPITAL.—Honorary Assistant Surgeon.
UNIVERSITY OF LONDON.—Examiners. One each in Medicine, in Surgery, and in Pathology.
VICTORIA HOSPITAL FOR CHILDREN, Tite-street, Chelsea, S.W.—House Surgeon for six months. Honorarium of £25, with board and lodging.
FORE DISPENSARY.—Resident Medical Officer, unmarried. Salary £120 a year, with board, lodging, and attendance.

Births, Marriages, and Deaths.

BIRTHS.

BEATON.—At The Cliffe, Bradford, on the 2nd January, 1906, the wife of Dr. Gilbert T. Beaton, of a daughter.
FAIRFIELD.—On Dec. 25th, 1905, at Mere, Wilts, the wife of William Walter Fairfield, M.R.C.S. Eng., L.R.C.P. Lond., of a daughter.
FORBES.—On Dec. 27th, 1905, at Oakwood-court, Kensington, W., the wife of J. Graham Forbes, M.D., M.R.C.P., of a daughter.
SOPER.—On Dec. 25th, 1905, at Clapham road, S.W., the wife of Bertram Soper, L.R.C.P. (nee Frances Ash), of a son.

DEATHS.

DASTY.—On Dec. 30th, 1905, at the Silver Birches, Epsom, William Clement Dasty, M.D., M.R.C.S., L.S.A., aged 65 years.
GRAY.—On 25th December, at 22, Anerley Park, London S.E., Thomas Gray, M.R.C.S. Eng., and L.S.A. (formerly of 12, Montague-place, Poplar, E.), in his 94th year.
GREENER.—On Dec. 26th, 1905, at Fallowden, Cathedral road, Cardiff, Michael Hindmarsh Greener, M.B., C.M.

N.B.—A fee of 2s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

NELSON'S FATAL WOUND.

WE give below a copy of a statement, written and signed by Surgeon William Beatty, commissioned on board the Victory at the battle of Trafalgar, who attended Lord Nelson after the receipt of the mortal wound. Surgeon William Beatty's "Authentic Narrative of the Death of Lord Nelson, with the Circumstances preceding the Happening and Subsequent to that Event" were published with a "Provisionary Report of his Lordship's Wound," and certain anecdotes, immediately after the tragic occurrence and the note that we now publish was probably one that was penned for his own use as an immediate memorandum. It bears the shape of a letter but it is not addressed to anyone and the date of the year is not stated. Mr Dudley Brown of Woodside, Surrey, found the original document among some old papers and to his courtesy we are indebted for the copy.

[COPY]

H M Ship Victory, 15th December

About the middle of the Action with the Combined Fleets on the 21st October last, the late illustrious Commander in Chief Lord Nelson, was mortally wounded in the left breast by a Musquet ball, supposed to be fired from the Mizen top of *La Redoutable* French Ship of the line which the Victory fell on board of early in the battle, his Lordship was in the Act of turning on the Quarter Deck with his face towards the enemy, when he received his wound, he instantly fell, and was carried to the Cockpit where he lived about two Hours.

On his Lordship being brought below he complained of Acute pain in about the sixth or seventh Dorsal Vertebra, of privation of sense and motion of the body and inferior extremities, his Respiration was short and difficult, his pulse Weak small and irregular, he frequently declared his back was shot through, that he felt every instant a Gush of blood within his breast, and that he had sensations which indicated to him the approach of death: in the course of an hour his Pulse became indistinct and was gradually lost in the Arm, his extremities and forehead became soon afterwards cold he retained his wonted energy of mind, and exercise of his faculties, until the latest moment of his existence, and when Victory as signal as decisive was announced to him he expressed his pious acknowledgments thereof and heartfelt satisfaction at the Glorious event in the most emphatic language he then delivered his last order with his usual precision and in a few Minutes after expired without a struggle.

Course and Site of the Ball ascertained since Death—The Ball struck the forepart of his Lordship's Epaulette, and entered the left shoulder immediately before the Processus Acromion Scapulae which it slightly fractured, it then descended obliquely into the Thorax fracturing the 2nd and 3rd Ribs and after penetrating the left lobe of the Lungs and dividing in its passage a large branch of the Pulmonary Artery it entered the left side of the spine between the sixth and seventh Dorsal Vertebrae fractured the left transverse Process of the sixth Vertebra wounded the Medulla Spinalis and fracturing the right transverse Process of the seventh Vertebra, it made its way from the right side of the spine, directing its course through the Muscles of the back and lodged therein, about two inches below the inferior angle of the right scapula.

On removing the ball a portion of the Gold lace and Pad of the Epaulette together with a small piece of his Lordship's coat were found firmly attached to it. Signed W BEATTY, Surgeon

Surgeon Beatty, who was knighted many years later by King William IV, became a distinguished man in the medical profession, was physician to the Greenwich Hospital until his death in 1842 and a Fellow of the Royal Society. In Munk's "Roll of the Royal College of Physicians" it is stated that Sir William Beatty, who became a Licentiate of the Royal College of Physicians of London in 1817, kept the bullet which killed Nelson in a crystal case, mounted in gold. Sir William Beatty, who was a young man when serving on board the Victory, died in 1842.

SANDOW DEVELOPMENT TREATMENT A WARNING

To the Editors of THE LANCET

SIRS,—This experience may interest some of your readers. Some weeks since I advised a lady patient that some physical development would be likely to be good for her and after considering the method to be adopted decided, for certain reasons that she should write for particulars of the above. The prospectus promised a year's treatment for five guineas and pointed out especially that although the charge might appear to be high it included a series of instructions, forwarded from time to time as to progressive exercises for a whole year. It also offered to accept three guineas for the first part of the treatment. The necessary form was filled up and sent, with a cheque for three guineas. In return a letter was received giving some very general semi-medical advice such as the advisability of taking wine in moderation and omitting the bath during the periods and with it a small book containing printed directions for a series of exercises to be done so many times a day for two weeks. After this the remainder of the five guineas became due.

I must admit that no statement was made as to the length of time of the first part of the treatment, but by implication one might reasonably have expected a good deal longer period than two weeks. *Careful employer* certainly—but it may be advisable that your readers should be in a position to explain the terms to any patients who are thinking of going in for this treatment. I am, Sirs, yours faithfully,
Dec 31st, 1905 J G

A CORONER ON MEDICAL MISSIONS

A RECENT occurrence at Bethnal Green throws a little light on the working of medical missions. A woman took a child to the Home of Industry Medical Mission, where she found that one of the medical officers was ill, and after waiting an hour was told that the other medical officer had wired that he too was disabled by illness. The child died from bronchitis and, an inquest was subsequently held by the coroner for North-east London Dr W Wynne Westcott, who is reported to have said "These medical missions cause much trouble. They attend people for minor ailments, but if the patient is taken worse there is no one to attend him. Another doctor is called in when the patient is dying, and so an inquest is caused. Any medical charity which does not have a medical man on the premises is a nuisance." It is doubtful whether there is any need for many of these so-called "medical missions." In many cases they are formed not so much for the purpose of relieving the sick poor but as an advertisement for some enterprise or other. It may be a chapel or it may be an industrial society but the object is the same in either case—viz., to attract support by the offer of cheap or gratuitous medical attendance.

COMMUNICATIONS not noticed in our present issue will receive attention in our next

Medical Diary for the ensuing Week.

SATURDAY (13th)—Royal Free (9 A.M.) London (2 P.M.) Middlesex (1.30 P.M.) St. Thomas's (2 P.M.) University College (9.15 A.M.) Charing Cross (2 P.M.) St. George's (1 P.M.) St. Mary's (10 P.M.) Throat, Golden square (9.30 A.M.) Guy's (1.30 P.M.) Children Gt. Ormond-street (9.30 A.M.)

At the Royal Eye Hospital (2 P.M.) the Royal London Ophthalmic (10 A.M.) the Royal Westminster Ophthalmic (1.30 P.M.) and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES

MONDAY (8th)—MEDICAL SOCIETY OF LONDON (11, Chandos-st. ch. Cavendish-square, W.)—8.30 P.M. Papers—Children's Diseases—(1) Dr E. Cantley. Chronic Membranous Colitis in Infancy. (2) Dr C. R. Fox. Bronchiectasis and Oesophageal Surgery. TUESDAY (9th)—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (23, Hanover-square, W.)—8.30 P.M. Papers—Dr A. Hall: Capillary Circulation and Blood Pressure and the Conditions that Control Them—Dr F. Taylor: Three Cases of Myoclonus.

WEDNESDAY (10th).—HUXTERIAN SOCIETY (London Institution, Finsbury-circus, E.C.O.).—8.30 P.M. Pathological Meeting.
DERMATOLOGICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish-square, W.).—5.15 P.M. Meeting.
THURSDAY (11th).—BRITISH GYNECOLOGICAL SOCIETY (20, Hanover-square, W.).—8 P.M. Annual General Meeting. The President (Dr. W. Alexander): Valedictory Address.
FRIDAY (12th).—CLINICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8.30 P.M. Papers:—Mr. L. McGavin: Transverse tears of Inguinal Colotomy. Mr. A. I. Pinches and Mr. E. M. Corner: Further Cases of Torsion of the Omentum.—Dr A. E. Garrod and Dr. Langmead: A Case of Associated Malformations including Transposition of Viscera.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (8th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—College opens.
POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Saunders: Examination of Stomach and Gastric Contents.
TUESDAY (9th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M. Dr. H. Campbell: Clinique (Medical). 5.15 P.M. Opening Lecture:—Sir Felix Semon, E.C.V.O.: Some Unusual Manifestations of Syphilis in the Upper Air Passages.
POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. S. Taylor: Errors in Treatment.
WEDNESDAY (10th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M. Mr. J. Cantile: Clinique (Surgical). 5.15 P.M. Lecture: Dr. G. H. Savage: Climacteric Insanities.
POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Boddard: Practical Medicine. (Lecture I.)
THURSDAY (11th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M. Mr. Hutchinson: Clinique (Surgical). 5.15 P.M. Lecture:—Mr. L. Mummery: Some Problems in Morbid Physiology.
POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Davis: Some Common Diseases of the Pharynx and Larynx. (Lecture I.)
FRIDAY (12th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M. Clinique. (Eve.)
POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. Lloyd: Anaesthetics. (Lecture I.)
NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—4.30 P.M. Opening Lecture:—Mr. J. Langton: Exploratory Laparotomy, its Objects and Limitations.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only. AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication. We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. II. of 1905, which was completed with the issue of Dec. 30th, are given in this number of THE LANCET.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1905 will be ready shortly. Bound in cloth, gilt lettered, price 18s., carriage extra.

Cases for binding the half year's numbers are now ready. Cloth, gilt lettered, price 2s., by post 2s. 3d.

To be obtained on application to the Manager, accompanied by remittance.

THE LANCET AT THE RAILWAY BOOKSTALLS.

READERS who usually obtain their copies of THE LANCET at the bookstalls on the Great Western, the London and North Western, and the minor systems in connexion with these railways, are requested to communicate with the Manager, 423, Strand, London, W.C., if they experience any difficulty in getting copies of THE LANCET at these bookstalls, Messrs. W. H. Smith and Son's connexion with them having now terminated.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsgagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.	TO THE COLONIES AND ABROAD.
One Year £1 12 6	One Year £1 14 8
Six Months 0 16 3	Six Months 0 17 4
Three Months 0 8 2	Three Months 0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

- Z.—Mr. D. N. Zanichelli, Bologna; Messrs. A. and M. Zimmermann, Lond.

TO ADVERTISERS.

The Manager regrets that, in consequence of the great demand made on the advertising columns of THE LANCET this week, he has been compelled to omit a large number of announcements (other than those for which space had previously been booked) which reached the Office later than Tuesday.

Three Clinical Lectures

OR

THE "ACUTE ABDOMEN."

Delivered at St. Thomas's Hospital

By, WILLIAM HENRY BATTLE, F.R.C.S. ENG.,

SURGEON TO THE HOSPITAL.

LECTURE I.

Delivered on Nov. 2nd, 1905.

GENTLEMEN,—There is no branch of surgery which demands greater consideration from you than that to which I ask your attention, for it comprises a group of cases some of which will certainly cause you much trouble and anxiety in future life. It is of the greatest importance, therefore, that you should have a good working knowledge of this subject from the clinical standpoint. The only way to obtain this is by taking advantage of your opportunities now whilst you are at the hospital. Obtain permission to examine every abdominal case that comes under your observation, if it is possible to do so, without injury to the patient. Do not be satisfied with the statement of others that such and such a sign is present; examine for yourselves and endeavour to appreciate it on your own account. Having examined to the best of your ability, try to come to a decision as to the meaning of the signs before you and do not fail to be present at the operation, if any, so as to confirm or disprove the diagnosis. At one time all we could do was to follow these acute abdominal cases to the post-mortem room, for they almost invariably went there, but with increased knowledge of the various conditions on which the acute abdomen depends, a better estimation of the value of local signs and symptoms, and a satisfactory operative technique, we now save many who in comparatively recent years would have been condemned to death from the manifestation of the first symptom. Upon your early recognition of the importance of symptoms many a life may depend, for whilst our medical papers show wonderful instances of recovery from advanced and apparently hopeless states of disease, which give encouragement to us even in desperate cases, they do not show the numerous others which have not responded to treatment equally skilful.

On thinking over the question of the subject for a clinical lecture the other day it seemed to me that it would be an advantage to recall some of the more important cases of acute abdominal disease which have been in the hospital under my charge during the past few months, especially choosing those in which operation revealed a definite lesion which could be regarded as the cause of the condition, the treatment of which led to the saving of the life of the individual. In the early stage of acute invasion of the peritoneum, or a serious lesion of it, there will be the signs of "peritonism"—that is, the patient will suffer from shock, local pain, and vomiting; there is then an interval of varying duration when the powers of the individual are being fully employed in rallying from the shock, combating the invasion, and limiting its spread. Probably a peritonitis will immediately commence and other symptoms be superadded as the inflammation extends and the toxins produced by the invading hordes of bacteria become to a certain extent absorbed.

An abstract from "Diseases of the Vermiform Appendix and their Surgical Complications" may be made to give you an idea—a general idea—of what the "acute abdomen" is like when the earlier symptoms have been misunderstood: "The general symptoms are those of a person who is really ill, unless these are hidden by the injudicious administration of morphia. The face is almost always anxious-looking. The pulse is increased in rapidity, the respirations are slightly more frequent than normal, and shallower, the respiratory movements being chiefly costal. The abdomen, to which the attention is mainly called, is distended, more or less motionless, tender on palpation, sometimes also on

percussion, and often presents the signs of free fluid, such as dullness in the flanks, which shifts on movement. Vomiting is almost invariably present, and after that of the onset may pass off a little, only to become distressing later. The tongue is usually furred and the breath often foul. The bowels are almost invariably without action both to feces and flatus. In many cases the onset of the attack is accompanied by a diarrhoea, often offensive; or a looseness of the bowels may be a late symptom, and is then called 'septic diarrhoea.' But there is always some difficulty in the passage of the contents of the alimentary canal caused by a growth, volvulus, band, segment or segments of 'paralysed gut, &c. A rectal examination should always be made, although in the majority of cases it yields a negative result. The urine is usually scanty; at first normal, later it may contain albumin, but rarely blood." This description may appear inadequate and it is necessarily so; there are hardly any two cases that are alike in the cause of the sudden illness and in the resistance of the individual. So that in one patient the general symptoms are of the greatest importance and must be relied upon as an indication for treatment, whilst in another the local signs indicate the dangerous nature of the illness.

You will naturally ask what are the signs and symptoms to be specially noted in any case coming under notice with this history of sudden abdominal pain, shock, and vomiting? I take it that what is really required is to give such indications as may be useful in showing you when the state of the patient is one which requires operation to point out the symptoms which cannot be neglected with any consideration for the patient's welfare. These I will give briefly.

In the first place, look with attention at the patient's face, for you will learn much from it. The colour in a case of acute abdominal disease will vary very much from that of a healthy person to the dusky flush of one whose respiration is embarrassed; the expression, from a placid indifference, to that of a man in mortal agony. Sunken eyes with dark circles round them, a pinched face, and an anxious expression are very ominous; if the nostrils are working rapidly you may be sure that the pulse is also going too fast and there is very serious disease present.

The pulse-rate is a very important indication as to whether the case may be safely left, it is advisable to operate, or the patient is too far gone for relief. If some hours have elapsed since the commencement of the attack and the pulse-rate is much too high there is nothing to be gained by postponing an operation; every hour lost renders a successful operation less probable. Any abdominal case with a pulse-rate of over 100 should be carefully watched; if it continues to rise beyond this the patient will probably require surgical aid, although other symptoms may be improving. The temperament must be considered in estimating the value of the pulse-rate, for occasionally a patient may be unduly excited by the medical man's visit or suffering from a neurosis.

The temperature is often misleading; there may be the most widely diffused septic suppuration with a normal or subnormal temperature. Usually there is a rise at first, but it should begin to fall on the second day. A low or sub-normal temperature and a rapid pulse is a very bad combination.

Vomiting should cease after the onset and its continuance is a bad sign. The effortless pumping up of large quantities of greenish fluid should cause much concern.

Restlessness is an unfavourable symptom; so, indeed, is a condition of manifest indifference and apathy. Usually you will find your patient lying on the back with the arms thrown above the head and the lower limbs flexed on the abdomen. This attitude is not, however, universal.

Look for the marks of recent applications for relief of pain; these will give you some idea of its severity. Examine the skin for signs of inflammation and oedema and when the abdomen is fully exposed note the amount of movement on respiration as naturally performed, and then ascertain how much the patient can voluntarily increase this. Find out the exact seat and character of the pain by asking the usual questions; also the history of previous attacks of a similar kind. Gently palpate so as to learn the condition of the muscles as regards rigidity, general or local, also the presence of any local tumour or undue resistance. Percuss the abdomen throughout, but with a light hand, paying great attention to the flanks and to the parts above the umbilicus. If there is any dull area try if it is affected by

moving the patient, as the presence of free fluid is a sign of importance. Define the liver dulness. Observe also the extent of distension of the intestines, the presence, or otherwise, of peristalsis, and whether this is local or general. If there appears to be some distension of the bowel find out if this is increasing in amount.

It is hardly necessary to remind you of the necessity of learning from the friends, the state of the bowels, if there is inaction or diarrhoea. But you should nearly in all cases make a rectal examination at once and in most this has to be repeated. You thus ascertain from the beginning if the contents of the pelvis are normal or not. In some instances you will find inflammatory swelling on the right side and in others an abnormal amount of tenderness. The extent of these will, of course, vary much with the nature of the case and the duration of the illness.

The number of cases of acute abdominal disease which are secondary to disease of the appendix naturally make us, in the first instance, consider the subject from the point of view of that part of the digestive tract. The relative proportions of the various factors in the causation of acute abdominal diseases are shown in the statistics of the cases under care in St. Thomas's Hospital during the three years 1900, 1901, and 1902.* In all there were 456 cases, of which 168, or 37 per cent., were from disease of the appendix, forming by far the largest class.

Acute Abdominal Cases.

Appendicitis and its complications	37 per cent.
Intestinal obstruction (other than intussusception)	24 "
Intussusceptions	16 "
Perforations of the alimentary tract	11 "
Pelvic or gynecological cases	6 "
Abdominal abscesses (other than appendicitis)	3 "
The remainder	3 "

The great importance of the rôle which the appendix plays is clearly shown by this table. The first four of the groups in the list are the most important and require special attention. They are worth consideration in the first place from the question of age, for given certain difficulties in diagnosis the probabilities will be in favour of intussusception during the first ten years of life, acute disease of the appendix between the ages of 15 and 30, perforations of the alimentary tract from 15 to 40, and intestinal obstruction from the age of 30 upwards, with increasing frequency to a maximum between 50 and 60.

The simple uncomplicated cases of inflammation of the appendix, and those which are ending in localised abscess, are far more common occurrences than is generally taught, are not under consideration to-day. My remarks are chiefly concerned with the cases in which the inflammation of the surrounding peritoneum is not only a septic one, but one which tends to diffusion, and ends fatally if unrecognised or wrongly treated. A discussion of all of the combinations of symptoms and signs which may be met with in cases where diffuse peritonitis is coming on is beyond the purpose of this occasion. I desire now to illustrate by the description of cases some of the more common. When the illness is ushered in with a rigor, severe vomiting, very acute pain, or other startling symptoms, the friends, as well as the medical attendant are alarmed and on the alert, but when the onset is rather indefinite and the patient does not appear very much worse from one hour to the other there is a danger that surgical assistance may be asked for when it is too late to do any good. I have seen this very often in cases of gangrene and perforation of the appendix when the extent and nature of the mischief were quite unsuspected.

The case of a boy, aged six and a half years, is a very good example of the type of which I am speaking. He was admitted to the Leopold Ward on March 30th, 1905, and left on May 20th. He first began to be unwell on March 27th, about midday, and was sick on the 28th and 29th. He had some abdominal pain and constipation but not very much pain. He was thought to have some stomach derangement and was given castor oil. Mr. E. T. Whitehead, who saw him on the morning of admission, thought seriously of his state and agreed with me when we saw the boy together about 12 o'clock that he had diffuse peritonitis secondary to disease of the appendix. The state of the boy at that time was as follows. He was a pale lad with light hair, lying in his bed partly turned to the right, and apparently quite comfortable. He did

not look very ill, smiled when spoken to, and answered questions about his name, age, &c., quite readily. He drew a deep breath when requested to do so and said that his chest did not hurt him; he admitted that he had had some pain in the stomach. When requested to turn in his bed fully he did so easily and with a smile. The abdomen was somewhat distended, not rigid, but with greater resistance in the right iliac fossa than in other parts. In the right flank running obliquely into the pelvis across the iliac fossa was a well-marked area of dullness, evidently, from its shifting character, due to fluid. His tongue was moist and clean; he had vomited the night before but not that morning. The bowels were confined. He had slept without morphine. The temperature was 99° F. but his pulse was 140. At the operation at 3 P.M. we found very offensive pus in the right flank and pelvis, quite unlimited by adhesions, and lymph on some of the coils of intestine in the iliac fossa and pelvis. The appendix was large, its walls were cedematous, there was a circular band of gangrene running round it about three quarters of an inch from its distal end, and in the mesenteric border of this part there was a perforation. On opening the appendix there was a concretion above and another below the gangrenous part. The subsequent history was briefly as follows. The bowels acted on the 31st after a turpentine enema and improvement followed in the condition of the abdomen, but he suffered from vomiting. Until April 2nd he was very ill, losing flesh and strength, with occasional vomiting of coffee-ground material. His pulse had come down to 100 and his temperature was 98°, but he seemed to have no "rally." On the 3rd this brown, offensive vomiting ceased at 3 A.M. Later in the day five grains of calomel were given with good result and he began to improve. Making steady progress from this time he was no longer a source of anxiety to us.

This case has been given because the symptoms were not those typical of the acute abdomen; the onset was insidious, but I think it is a very important and excessively dangerous type. Operation was only just in time, and I feel confident that if it had not been for the skill and devoted attention of the sister of the ward he would have slipped through our hands, for his state was very serious for some days afterwards. In these cases a slow absorption of toxin takes place by the lymphatics of the peritoneum, and it may be only when renewed vomiting is added to the rapid pulse that the gravity of the case is appreciated. How often do we hear it said, "but I never suspected it; he had so little pain and seemed so well."

A more typical example of acute abdominal disease secondary to appendix mischief is the following. A school-boy, aged 11 years, was admitted to St. Thomas's Hospital, under the care of Dr. Hector Mackenzie, on Jan. 25th, 1905. His illness began four days before (on the 21st) during the night with acute pain in the right side of the abdomen; on the following day he was much worse. He also felt sick and vomited everything he took. His bowels were constipated and remained so until admission. The vomiting and pain in the abdomen continued. On admission he had a pinched, anxious-looking face and complained of pain in the abdomen, chiefly in the lower part on the right side. He was lying on his back with his legs drawn up. The abdomen did not move at all in the lower part and there was only a slight movement in the epigastrium and upper part. On palpation great tenderness was found all over the lower part, especially in the right iliac fossa. The abdominal muscles were rigid and a swelling was detected in the right iliac fossa, extending upwards from Poupart's ligament. This swelling could not be defined accurately owing to the muscular rigidity. On percussion dullness was present over this swelling and also in the left flank. The rest of the abdomen was resonant. The pulse was 100, the respirations were 20, and the temperature was 100.6° F. In contrast with the case of the other boy, who was quite non-resistant to his disease and indifferent to his surroundings, this patient was restless and protested vigorously against operation. At the operation free pus in considerable quantity was found in the peritoneum. There was much deposit of lymph on the peritoneum covering the small gut, which was generally reddened; in some places hæmorrhagic patches could be seen under this lymph. The purulent fluid filled the pelvis and extended into the right flank. The appendix was three inches long, thick, and fleshy, with gangrenous mucosa. There was a concretion in the central part and just below it a minute perforation externally plastered with fibrinous lymph. The peritoneal cavity was

* Loc. cit., p. 135.

washed out with warm saline solution; some of the lymph was gently removed with gauze sponges; a drainage-tube was inserted and also a gauze plug. After the operation the patient's sickness ceased; his pulse gradually fell to normal but was still 103 on Feb. 8th, 14 days after operation. At first he was peevish and difficult to please but left the hospital quite well on March 17th.

You will perhaps be called upon to give your opinion in a case in which, for a time, there has been a very evident improvement and the friends of the patient naturally want to know if the dangerous stage is not passed and safe convalescence assured. "He is so much better!" Here you must be guided by various considerations. At the hour when I should have been addressing you on this subject a month ago I was engaged in operating on a most instructive case, a brief note of which is here given.

On Oct. 2nd the patient, a previously healthy girl, aged 19 years, was slightly troubled with diarrhoea, the cause of which was not known. On the morning of the 3rd she was awakened the first thing by severe pain in the lower abdomen. She vomited throughout the day, being unable to retain any nourishment. The bowels did not act. She was kept in bed. On the 4th there was a severe attack of vomiting and diarrhoea at 3 A.M. and the pain persisted. When she was first seen the abdominal movements were very slight. There was general tenderness, especially in the epigastric and right iliac regions, but the abdomen was not very rigid. The tongue was coated and rather dry. The pulse was 136 and the temperature was 100° F. At 9 A.M. on the 5th the tenderness was rather more marked in the right iliac region than elsewhere. The abdomen was more distended and harder to the touch. Per rectum the chief tenderness was to the right; there was no tumour. Vomiting had ceased at 3 A.M. The pulse was 120 and the temperature was 99·6°. About 12.30 P.M. she was flushed and looked rather tired but was quite cheerful and clear headed. The tongue was furled; it had been dry. No morphine had been given. The abdomen was slightly distended, generally tender, not moving well, and the patient was unable to draw a deep breath. There was tenderness, especially in the right iliac fossa; the right rectus muscle in its lower part was somewhat fixed. On percussion there was dullness in the right flank and more resistance than elsewhere, but no definite swelling. Otherwise the abdomen was normal. The pulse was 140.

An operation was performed as soon as possible. Free purulent fluid was found on opening the peritoneal cavity and thick pus filled the pelvis; this was very offensive. The appendix was turned upwards and to the left and was adherent to the under aspect of the umbilical region. It measured about three and a half inches in length, was fleshy and contained a large concretion; below this was a patch of gangrene and in the mesenteric border of this patch there was a perforation. The pelvis was carefully cleaned with dry aseptic gauze. Some pus was removed from both flanks. The coils of intestine in the pelvis were covered with thick lymph which adhered closely and it was only sponged away where it was lightly adherent. A gauze plug was inserted and the pelvis was drained. On the 8th the patient was doing extremely well. The pulse was 60. There was no pain. The temperature was normal. The bowels acted after calomel. The abdomen moved satisfactorily and was no longer tender. The plug was removed and the glass tube was replaced by a rubber one. She has made a good recovery.

The reason why no one was consulted at the commencement of the illness was that as the patient always suffered much at the commencement of the period, and this was due on Oct. 3rd, her pain was put down to that. The period came on at the proper time but without relief of the pain. It was then recognised that the period was not responsible and that the patient had some severe illness. Here it was the rising pulse on the fourth day of illness more than anything else that induced us to urge operation on the relatives, for beyond this there was no unfavourable sign. Had there been a definite swelling in the iliac fossa or pelvis perhaps one would have felt less certainly of the need for immediate operation, for it would have been probable that some attempt at localisation was taking place. All the other symptoms were quite satisfactory.

In yet another case, also seen in consultation away from the hospital, after a definite attack of severe pain, the patient was apparently quite recovered from the peritonitis and felt perfectly well. Here the verdict in favour of operation was given because of the excessive rigidity of the lower

part of the right rectus which a dose of morphine had not in any way diminished. The patient, a man, aged 32 years, was seen with Dr. G. G. Davidson about 10 o'clock in the morning of March 15th, 1905. He had complained of some stomach ache on the previous evening and vomited after a dose of castor oil. He then sent for Dr. Davidson who, knowing that he had had a mild attack of appendicitis two years previously, examined him very carefully. The man had a normal temperature and natural pulse-beat and the only thing unusual was tenderness above Poupart's ligament on the right side. The pain was not very severe, so no medicine was given to make him sleep, but he went to bed earlier than usual and slept until 4 A.M. on the 11th, when he was awakened by a severe pain in the abdomen. He again sent for Dr. Davidson who found him suffering severely and gave morphine to relieve the pain. The pulse was then 70 and the temperature was normal. At 10 o'clock, when we met, the patient had been sleeping and the pain was completely gone. His expression was good. The pulse was 60, the respirations were 20, and the temperature was 99·6° F. The tongue was thickly coated but moist; the bowels were confined. The abdomen was rather rigid generally but not distended. Tenderness was complained of on pressure in the right iliac region but the lower part of the right rectus was so very hard and rigid that nothing could be felt in the iliac fossa. The percussion note in this region was impaired but it was difficult to define any dull area.

Immediate operation was advised and performed. There were some ounces of pus diffused in the iliac fossa and pelvis, with peritonitis affecting the coils of small intestine in the area exposed, some of which were covered with lymph. The appendix was large, measuring five and a half inches in length and about one and a half inches in its greatest transverse diameter. It was much distended and discoloured, being gangrenous in places. There was a stricture of the proximal end and beyond that was the distended portion; the gangrenous wall had given way in two places—one of these openings was partially blocked by a stercolith. Three other stercoliths were present and the whole of the mucous lining was gangrenous. The appendix was difficult to bring to the surface and could not be lifted until its attachments had been divided. The peritoneum was very sensitive; during the operation pulling on a coil of small intestine or sponging the peritoneum caused at once a change in respiration, and it may be that this unusual degree of sensitiveness was accountable for the paralysis of a part of the small intestine near, which subsequently developed, causing subacute obstruction. All inflammatory symptoms ceased after the operation; the temperature remained normal, whilst the abdomen remained without distension or pain, and the bowels acted, but nothing appeared to relieve the patient of his sickness.

A second abdominal incision a week later showed the complete absence of peritonitis and disclosed a portion of small intestine about 12 inches in length near the right iliac fossa, which was flaccid, and above which the gut was distended. This was emptied through a puncture which was then closed, but the patient did not survive many hours.

In this instance, then, the patient suffered from the local effects of the acute mischief and not from the general result of the absorption of toxins. Dr. Davidson deserved success, for no one could have been more prompt in the recognition of the severity of the case or have treated it with more skill than he showed.

We are told by some surgeons that the removal of the appendix should be carried out immediately in all cases when signs of an attack of appendicitis are recognised. This may be called the counsel of perfection. The public, which has become somewhat familiar with the disease in its milder attacks during the past few years, can tell you of so many friends who have recovered without operation that the suggestion is scouted as soon as made. You cannot with a good conscience say that the attack will not in all probability pass over without risk of life in the majority of those treated by you. What I do think is that your duty as a medical adviser renders it imperative that you should be so skilled in the recognition of the various aspects of the disease that you should be able to say without doubt when immediate operation is imperative, not only when it is advisable. There are quite sufficient proofs in the hands of the profession that such excellence can be attained. My advice to you is to endeavour to reach it. So many of these acute cases come into hospital at night that you must be prepared for some

self-sacrifice if you wish to gain all the good you can from your hospital opportunities.

There is another thing that should be remembered and it is not only the need for operation in these serious cases but for early operation. A few hours may make all the difference between a life saved and a life lost. Do not behave with over-anxious fussiness that shows your alarm to the friends, if you conceal it from the patient himself, but see that sufficiently frequent visits enable you to observe the earliest signs of any unfavourable change. There are undoubted recoveries on record from an acute septic general peritonitis, but they are not so numerous as published cases would have us believe. There is a difference between "diffused" and "general" which is, I am afraid, not always appreciated by those who write and talk of their own cases.

In the remarks that I have made to-day I have only mentioned a few cases which have been under my personal observation; as you know, there have been some which have been treated by other surgeons in the same wards with equal success. They may have been as instructive as their treatment was successful but they cannot be quoted here as I did not see them. I have not mentioned cases of peritonitis which presented no prospect of recovery from the time of admission (the too late type); they would not do more than emphasise what I have endeavoured to impress upon you—the importance of the early recognition of symptoms, and promptitude in acting upon them in the conditions on which the "acute abdomen" when due to a diseased appendix depends.

In the consideration of the acute abdomen and its relationship to disease of the appendix there is another way in which a most serious condition may arise and that is through the bursting of an appendix abscess into the peritoneal cavity. This is a most formidable complication to control and until a few months ago it was in my experience invariably a fatal one. As you are aware, in cases of appendix suppuration there is an attempt made by nature to localise the pus; occasionally for some reason this is only successful for a time and there is a further spread of the pus and involvement of more of the peritoneum. This appears to take place slowly and is not accompanied by the definite signs which we have spoken of as peritonism. A very different clinical picture is presented by the patient in whom an abscess containing a large amount of pus has suddenly burst, distributing its septic contents throughout the abdomen.

Examples of this complication of appendix abscess have been under treatment during the past few months; they are very instructive and give hope for the future. Altogether four such cases have been under care since July, 1904. They are as follows:—

CASE 1.—In this case, that of a boy, aged 16 years, the abscess ruptured whilst he was lying, preparatory to operation, in the male medical ward. There was great shock and at the operation there was a quantity of purulent fluid generally diffused. The operation was not successful in saving life and the patient died in a few hours from general peritonitis.

CASE 2.—The patient, aged 19 years, a ward maid at a fever hospital, was admitted under the care of Dr. Mackenzie on Nov. 3rd, 1904. Her illness commenced with pain in the right iliac region seven days before admission; she was obliged to go to bed, but resumed work on the following day, and did her usual duty as well as she could until 16 hours before she came in, when a sudden acute pain attacked her and she was again obliged to go to bed. There had been diarrhoea for two or three days. When seen with Dr. Mackenzie she was propped up in bed; her nostrils were working rapidly and she was breathing with some difficulty; her face was dusky and anxious-looking. She was somewhat restless but quite clear in her mind and able to answer questions. Her respirations were 32, her pulse was 100, and her temperature was 100.6° F. The lower abdomen was distended and did not move at all on respiration; the upper half moved moderately. On palpation there was a marked resistance in the lower half of the abdomen, especially over the right iliac fossa, where there was a definite swelling. There was great tenderness here but the abdomen was generally tender. On percussion dullness was found in both flanks but not above the pubes. The liver dullness was obliterated. The respiration was thoracic and shallow; the tongue was furred and dirty.

Two incisions were made, one through the right rectus and the other in the left linea semilunaris. The abscess was

found to have given way on the pelvic aspect and the pelvis was filled with offensive semi-purulent fluid which was generally diffused throughout the lower part of the abdominal cavity. Lavage with warm saline solution was carried out and drainage through both openings. The patient made a good recovery and left hospital on Dec. 15th. The appendix was excised on Jan. 18th, 1905. It was two inches long. A stricture was situated half an inch from the tip, below which had been a small perforation; it was adherent to the caecum. The omentum was adherent to the old cicatrix, otherwise there was nothing unusual.

CASE 3.—The patient, a man, aged 33 years, was sent to the hospital by Mr. S. R. Hallam and was admitted under the care of Dr. Mackenzie on Nov. 4th, 1904. He had had an attack of pain in the abdomen on Oct. 31st, chiefly on the right side, but did not give up his work. During the night of Nov. 3rd an attack of intense pain was experienced and he came to the hospital in the morning 16 hours later. When examined he was found to be perspiring freely; his face was pale and anxious looking and his respirations were shallow and diaphragmatic. An attempt to breathe deeply caused him much pain in the abdomen. His pulse was 104 and his temperature was 101.2° F. There was no vomiting. The bowels were confined. The abdomen did not move on respiration and was very tender on examination, especially in the right iliac region and in the loins. There was dullness in the flanks and the liver dullness was obscured. The abdominal muscles were rigid, this rigidity being most marked on the right side. In the right iliac fossa there was an ill-defined swelling. At the operation two incisions were made, one through the right rectus muscle and the other through the middle line below the umbilicus. Offensive, semi-purulent fluid was generally diffused throughout the peritoneum. The intestines looked very congested and cedematous. The abscess had ruptured to the outer side. Lavage with saline fluid of a temperature of 110° was thoroughly performed, the hepatic and splenic regions being carefully irrigated. Drainage was employed from both wounds. These were closed by Dec. 17th. On Jan. 4th, 1905, the appendix was removed. It was one and a half inches long and contained two strictures, proximal and distal; the lumen at the extremity was obliterated. There were evidences of a former perforation below the distal stricture. The appendix was coiled up beneath the caecum in a mass of adhesions.

CASE 4.—The patient, a married woman, aged 34 years, was sent to the hospital by Mr. C. Dwight Morris of Feltham on March 22nd, 1905. On March 15th she began to feel ill with pain all over the abdomen. The day before admission the pain became suddenly much worse and she vomited a good deal, but it was not until the day of admission that it became localised to the right iliac fossa. The vomiting continued. There had been no previous attack of severe pain in the abdomen but she had suffered at times from indigestion and wind. The face was flushed and appeared somewhat anxious and drawn. The abdomen was distended in the lower part, especially in the right lower quarter. The distension was not great, but movement on respiration was very poor in the lower half. The abdominal wall was unusually flaccid and a swelling was detected in the right iliac fossa extending upwards from the outer half of Poupart's ligament. There was a good deal of tenderness on pressure over this swelling; the rest of the abdomen was also tender but only to deep pressure. Around and below the umbilicus coils of intestine were seen with occasional peristalsis. On percussion dullness was detected in both flanks and in the iliac fossa. The liver dullness was normal, the temperature was 101.6° F., and the pulse was 124. At 8 P.M. the abdomen was opened through the right rectus muscle. A small quantity of purulent fluid welled out and a large collection was found in the pelvis; flakes of lymph were found in various places adherent to the intestines which were red and inflamed. The thickening in the iliac fossa was composed of coils of small intestine which had limited an abscess cavity, the pus from which had mostly escaped through an irregular opening to the outer side. Below this opening, extending outwards and upwards, was the appendix, the separation and removal of which were readily effected. It was much swollen and presented a perforation about the middle of its length, the result of gangrenous ulceration. Two small concretions were found free outside the appendix, which was not strictured. The peritoneal cavity was thoroughly washed out with sterilised saline solution (110°). A glass tube was passed into the

pelvis and a gauze drain was placed above the opening into the iliac abscess cavity. A few fish-gut sutures were then employed to bring the edges of the wound together. In the evening the pulse was 100, the temperature was 99.2° , and the respirations were 24. The gauze drain was removed on the fourth day, the glass tube was replaced by a rubber one on the seventh, and this was replaced by a gauze strip on the fourteenth. The wound slowly closed and the patient was able to get up on May 9th, leaving hospital on the 15th. She had no pain after the operation but her temperature, although never high, did not become normal for the whole 24 hours until April 2nd.

A Lecture

ON

THE INSTITUTION AND SANATORIUM TREATMENT OF PULMONARY TUBER- CULOSIS IN RELATION TO LARGE CENTRES OF POPULATION.

Delivered at the Mount Vernon Hospital Post-Graduate
Course on Jan. 18th, 1906.

By E. F. TREVELYAN, M.D., B.Sc. LOND.,
F.R.C.P. LOND.,

HONORARY PHYSICIAN (WITH CHARGE OF OUT-PATIENTS) TO THE LEEDS
GENERAL INFIRMARY; HONORARY PHYSICIAN TO THE LEEDS
TUBERCULOSIS ASSOCIATION; PROFESSOR OF THIRA-
PEUTICS IN THE UNIVERSITY OF LEEDS.

GENTLEMEN,—The death-rate in the city of Leeds, which has a population of over 450,000, was 15.3 per 1000 during 1905. Of these deaths no fewer than 1.23 per 1000 were due to pulmonary tuberculosis, for 558 individuals succumbed to this disease. During this time there must have been at least three or four times that number—viz., from 1660 to 2200—of individuals actually suffering from pulmonary tuberculosis in Leeds. Dr. J. Spottiswoode Cameron who has kindly furnished the above figures also tells me that the death-rate from this disease has diminished during the past three quinquennial periods—from 1.50 in 1891-95, 1.45 in 1896-1900, to 1.32 in 1901-95. This number of consumptives is undoubtedly largely recruited from the poorer classes in the community. It is this class of phthisical patient about which I propose to speak to-day, and what I shall have to say will be largely based upon an experience obtained by an intimate connexion with the Leeds Tuberculosis Association since the time of its foundation in 1899. This association has now 70 beds at its disposal, 34 of which are used for early cases at the Gateforth Sanatorium and 36 for advanced cases at Armley Hospital. It is only too obvious that these small numbers are totally inadequate for the purpose and we look forward to further extensions. The scheme has, however, furnished us with some useful experience and it enables one to get an idea of what is really required if we are to grapple effectively with the morbidity and mortality caused amongst us by pulmonary tuberculosis.

By institution treatment I understand the treatment of this disease in institutions specially set aside for the purpose. We all know how unsatisfactory is the out-patient treatment of the disease in large general hospitals; at any rate, an 11 years' experience of it has brought this fact sufficiently home to me. It consists of the routine treatment of the appetite and of digestive disturbances, the provision of substitutes for food which many are unable to obtain at their own homes, the sedative treatment of cough, &c. The course of the cases is a chequered one but the tendency is nearly always in a downward direction and eventually they drop out. If one is able to follow them up, as in a public dispensary practice, one generally finds that they have died and not a few unexpectedly—that is, somewhat early in the disease.

Any scheme which adequately deals with the prevention and treatment of pulmonary tuberculosis in our large centres of population should include (1) an institution or sanatorium

for the earliest cases; (2) an institution or home of rest for advanced cases; (3) a hospital for cases intermediate between these two classes; and (4) a city office, including an out-patient department. In the Leeds scheme we have three out of these four essentials, but our out-patient department does not yet include the treatment of our patients but only the examination and observation of them. We have no hospital in the sense which I shall explain later and everything we have is much too small for its purpose.

1. *The sanatorium for the earliest cases.*—This brings me at once to the question of the value of sanatorium treatment for the poorer members of the community. At the present time no one would, I take it, contend that the sanatorium treatment of pulmonary tuberculosis is an ideal one. Among its disadvantages may be mentioned that the treatment must be prolonged, that it is expensive, and that it almost necessitates an enforced idleness which may be, and often is, demoralising. Permanent recovery can only be expected in the earliest cases taken from the phthisical poor of our large communities. This does not mean that nearly all cases, early or otherwise, will not receive obvious and great benefit from the open-air treatment—quite as great benefit as is derived from the hospital treatment of many chronic diseases, but they are not, and cannot be, looked upon as cured or, to speak more euphemistically, they will relapse when they return to insanitary homes where the necessities of life are far from plentiful. The discharged patient may be fit for work, but the competition in the labour market is keen and the delicate (including the phthisical) cannot compete with the sound. This we have seen over and over again even in cases where the prolonged idleness has not had the effect of making an individual disinclined to work. These facts make it all the more necessary to select the *earliest* cases from among those who apply to us for sanatorium treatment if we are to make the best use of our small sanatorium.

Selection of patients for sanatorium treatment.—My practice is to divide these patients into the febrile and non-febrile and the latter into four groups, according to the extent of the disease. Thus a patient who has a temperature verging on or above 101° F. would not be admitted even though the physical signs were slight. We make some provision, as will be mentioned later, for a few febrile cases in our other institution and if the temperature subsides they may be transferred to the sanatorium later. The non-febrile cases are further divided into bilateral and unilateral. This division is based on physical signs and obviously may not be really correct, as the existence of a lesion no doubt precedes the physical signs, but it forms a useful basis of classification. The non-febrile and unilateral cases are further subdivided into three groups.

Group I.—Cases in which the physical signs are slight and limited to the extreme apex. A thorough examination of all parts of the chest is made as not only the presence of the disease must be ascertained but also its extent. Diminished and delayed movement, an impaired percussion note (especially over the clavicle and inner part of the first interspace), an alteration of the breath sounds in the direction of bronchial breathing (broncho vesicular and vesiculo-bronchial breathing), and weakening of the breath sounds are carefully looked for. I am led to attach much importance to this weakening of the breath sounds. It is often very well marked in the downward extension of the disease towards the base of the lung, and frequently with increased vocal vibrations. I have very clear recollection of a boy repeatedly examined who had this weak breathing at the left base and no other physical signs. I thought that there might be something pressing on the left bronchus—possibly tuberculous glands—as there were enlarged glands in the neck. In a few months' time the whole broke down into riles and the case was clearly one of basic phthisis. The inspiration may be roughened, suggesting its early breaking down into riles. We need to diagnose the disease early, even if possible in a pre-rile stage. As regards stethoscopes my own preference is for the phonendoscope. Sometimes I make use of two instruments, each one specially connected up with a rubber tube and ear-piece. This is a cumbersome arrangement, but it appears at times to furnish additional information in comparing the physical signs on the two sides or in examining an apex simultaneously from the front and the back. In Group I. I also include cases where there are no definite signs but where there is other evidence making the presence of pulmonary tuberculosis certain, or almost

be kept practically empty of patients during the day. In this way the risks of infection, reinfection, and secondary infection are reduced to a minimum. The patients, with some exceptions to be mentioned later, are in the advanced stage of the disease or the subject of some serious complication such as laryngeal tuberculosis. Indeed, the advanced stage of the disease and poverty should together be the chief claims of the patient for admission into the home.

The improvement which even the advanced case will often undergo is quite remarkable; I have seen patients with physical signs of disease over the whole of one side and a considerable part of the other put on nearly two stones in weight. The diet is a generous one, better than that of a general hospital, but not quite so good as that of a sanatorium. Last year the average cost of the patients per head per day was 3s. 4d., as against 3s. 7½d. at Gateforth, the office expenses being 3½d. The relief of symptoms which these patients (accommodated as they often are on verandahs) experience even towards the end of life, is striking. The occurrence of night sweats is quite exceptional with us and then they only occur on isolated occasions. I never need to use drugs for them. The dyspeptic symptoms are often relieved. Diarrhoea is not common with us. It is treated in the usual way and particularly with copper sulphate and opium. The cough may abate but it mostly requires treatment at night. When morphine does not satisfactorily control it, syrup of codeine or a linctus containing heroin is used. Severe hæmoptysis has not been as common as one might have expected, considering the class of case admitted. I have thought that nitrite of amyl has been of service in its treatment. I have used chloride of calcium in some cases of recurrent and persistent hæmoptysis but its usefulness was open to doubt. Not a few of these advanced cases have very little pyrexia. When this exists rest in bed undoubtedly moderates it but in some cases rest in bed, sponging, phenacetin, &c., have little effect upon it. I have only seen in one or two isolated cases any real improvement in the physical signs. In the treatment of tuberculous disease of the epiglottis giving rise to much difficulty of swallowing I believe that amputation of the epiglottis is a proper method of treatment and I intend to try it. Mr. H. S. Barwell kindly allowed me to see some of his cases in the Mount Vernon Hospital at Hampstead in which much relief had resulted from this treatment.

I have tried intravenous injections of iodoform in one case only but the disease steadily went on extending so that I was not encouraged to try this method again. I may say here that I have no experience of the tuberculin treatment of pulmonary tuberculosis and up to quite recently I have been quite disinclined to try it in any stage of the disease, but Professor A. E. Wright's valuable researches into the subject of the opsonins have shed a new light upon it. It is a matter which must engage the attention of all those who have to treat phthisis.

Death has nearly always been preceded by attacks of difficulty of breathing. These attacks become more severe, the patient ultimately dying in one. Our Armley institution is, as I have said, intended for advanced cases but the rules allow the admission of a few acute early febrile cases. These cases are treated in shelters and on verandahs even for long periods of time if there is any chance of permanent good resulting. If the fever subsides and the patient's condition warrants it he would be transferred to Gateforth. The home of rest must necessarily be much more accessible than the sanatorium need be. In Leeds it is accommodated in a large adapted mansion and grounds in the higher parts and near the confines of the town.

3. In the selection of cases for Gateforth Sanatorium on the one hand and for the Armley Home of Rest on the other it only too often happens that many have to be rejected for the sanatorium whose disease is not sufficiently advanced to make them eligible for a home of rest. This intermediate class of case may diminish as cases are recommended or apply to us earlier in the disease, but still it cannot disappear. For these intermediate cases it seems to me that another institution is required. It should not, in my view, be a part of the home of rest nor yet of the sanatorium, or at any rate these cases should not be housed under the same roof as the advanced or the early cases. This third institution would be a hospital for consumptives. The stay in it would be comparatively short—say, from six to eight weeks. The patient would be carefully instructed in what he has to do to avoid spreading the disease to others. He would no

doubt improve during his stay in the hospital; it would give a short breathing time to those who are keeping the home together and it would permit of the house being thoroughly disinfected. The object of this hospital would be largely, but not wholly, preventive in character and educational. Febrile cases would be treated here and their subsequent course would determine what should eventually be done with them. Suitable provision could also be made here for the observation of suspected cases of pulmonary tuberculosis for the purposes of diagnosis. Only a short stay would satisfy this requirement in the majority of doubtful cases. The hospital would need to be accessible and situated in as healthy a part of the town as possible, preferably near its boundary.

4. A city office, including a board-room and an out-patient department, would complete the scheme. This must be situated in the centre of the town.

As an integral part of any scheme for dealing with pulmonary tuberculosis in our large centres of population the prevention of the disease must receive close attention. It is most important that the medical officer of health should be in close contact with the scheme. Fortunately our medical officer of health (Dr. J. S. Cameron) is on our committee and gives us valuable help. We supply the sanitary office with the names and addresses of all patients who apply to us for relief. Thus, when a patient is removed to one or other of our institutions his house can be disinfected. The list of discharged patients is also furnished to the sanitary office, so that they can be kept under observation. Cards with printed instructions on them are given to every applicant at the office and he is invited to buy at cost price spit-bottles and paper handkerchiefs. These articles are presented to those who cannot afford to buy them. Rules as to how the patient is to deal with his sputum are posted up in the wards of our institutions. A clear violation of these rules after a warning leads to the discharge of the offender.

The above scheme may seem to be a somewhat elaborate one. The prevention and treatment of pulmonary tuberculosis is, however, a complex and at the same time a costly undertaking, but with the present mortality from this disease, surely it is worth the labour and the money spent upon it if only we succeed in reducing the heavy death-rate from a disease which should, at least from the theoretical aspect, be completely preventable.

Remarks

THE EVOLUTION OF OPERATIVE GYNÆCOLOGY,

Being a Valedictory Address Delivered at the Annual Meeting of the North of England Obstetrical and Gynaecological Society at Manchester on Jan. 19th, 1906.

By D. LLOYD ROBERTS, M.D. ST. AND.,
F.R.C.P. LOND.,

PHYSICIAN TO ST. MARY'S HOSPITAL, MANCHESTER; CONSULTING
OBSTETRIC PHYSICIAN, MANCHESTER HOTAL INFIRMARY;
LECTURER ON CLINICAL OBSTETRICS AND GYNÆCOLOGY AT THE VICTORIA UNIVERSITY.

GENTLEMEN,—In the early days of an operation which is intended to remove some defect the operator aims directly at the object to be fulfilled. He roughly estimates the difficulties and dangers, many of which he cannot foresee, as the route he is taking has never been traversed before. His is not the lot to elaborate and to devise improvements the necessity for which is as yet unknown. Hence, early methods are crude and devoid of niceties of execution. Then improvements are added and improvements on improvements, until simplicity is overlaid with complexity. For a time the attention of operators is directed towards combating one or other of the many difficulties they or their predecessors have encountered. Their efforts are solely expended on details, to the surmounting of isolated obstacles, frequently to the neglect of the "unities" of

the operation. When this has gone on for a time a reaction sets in. Complicated methods are abandoned and a return is made in the direction of the primitive simplicity shorn of its crudities. It is interesting to note how this striving after perfection in operative procedure is cyclical in its course; it forsakes the primitive simplicity and makes for complexity, and when furthest from its starting point it tends to return there. Crude directness of purpose gives place to elaboration of method which, in its turn, yields to that effective simplicity which represents the high water mark of applied knowledge.

In few matters is this more forcibly shown than in surgical operations on the abdomen which involve exceptional difficulties owing to the close contiguity of many important organs and to the fact that the whole procedure takes place in a cavity into which only a limited access is obtainable. Beyond this there is the risk of hæmorrhage and of the possible escape into the abdominal cavity of exudative products from the tissues dealt with by the knife. Take, for example, Cæsarean section; suturing of the uterine wound was performed as far back as the beginning of the last century and even earlier, one or, in some instances, three sutures being used. Subsequently suturing fell into disuse. I can remember many years ago discussing with one of the greatest authorities of the day on Cæsarean section, my colleague, Thomas Radford, the question of suturing the uterine wound, when he spoke strongly against suturing, stating that the unaided contraction of the uterus was sufficient to prevent leakage from its cavity. At the present time suturing the uterus is regarded as one of the chief means of securing success, but then the mode of applying the sutures has been vastly improved since the days when one or two were deemed sufficient. Whilst suturing the uterine wound was still a debateable point the enormous fatality of Cæsarean section induced Porro to put into practice an operation he devised for the total removal of the gravid uterus. The principles of this operation had long before been suggested but had never been tried in the human subject. This operation, as a premeditated operation, was first performed by Porro in 1876. Its success led to a material reduction in the mortality of the operation for the delivery of women with pelvic obstruction so extreme as to be incompatible with the passage of a child, but exception was taken to it as a mutilating operation which deprived the woman of her natural functions. A return was then made to the primitive mode of abdominal delivery. Improved methods were devised which greatly reduced the mortality of the operation and at the same time avoided removal of the uterus. It was at this period that attention was specially directed to the suturing of the uterine wound. Amongst the modifications in the mode of applying the sutures may be mentioned those of Frank, of Kehrer (in which the uterus was incised transversely about the position of the internal os), and of Sänger; in all of them the apposition of the edges of the uterine wound claimed the most attention. Kehrer advised double sutures; some deep seated for the union of the muscular wall; others superficial to bring the peritoneal aspect of the wound into apposition. Sänger went further; he separated the peritoneum round the wound from its muscular bed and then pared a wedge-shaped strip of tissue from the edges of the wound and inserted deep sutures in such a way as to include the muscular coats whilst avoiding the mucous membrane; the edges of the peritoneum were subsequently more accurately united by superficial sutures placed closely together. The object was to make a sound impermeable closure. Here we have a return to sutures after they had been entirely abandoned. These improved methods of performing Cæsarean section have inverted the previous rates of recovery and of mortality: formerly the mortality reached 70 to 80 per cent.; at the present time the recoveries number 80 per cent.

As another example of returning to previously relinquished methods in the course of operative evolution, take operations on the cancerous uterus which in the first instance were performed through the abdomen. In 1828 Blundell removed the entire uterus through the vagina for cancer but the results were bad and the operation was abandoned. After this the cervix only was attacked through the vagina. Then return was made to total removal with improved methods: ligatures were applied before the structures were divided and after removal of the uterus the vagina was packed with gauze which acted as a drain. The latest method of removing the cancerous uterus is that of Wertheim, through the abdomen, the primitive path for the removal of uterine tumours. Again, the cure of vesico-vaginal fistula was performed in the early part of the last

century by simply paring the edges of the opening and bringing them together with ordinary sutures. Then silver wire was substituted, then split leaden pellets placed over the sutures were squeezed together so as to grip the sutures in place of tying them. Bozeman introduced metal plates with a series of holes through which the sutures were passed and the pellets fastened on. This was done in order to prevent the pellets being buried in the tissues by inflammatory swelling. All these modifications were found to be needless and injurious. At the present time silkworm-gut or catgut sutures are used in the ordinary way, which is practically a return to the original method. The complicated modes of uniting the ruptured perineum with quilled sutures and other elaborate devices have in their turn given place to the original simple suture.

The mode of dealing with the stump of the pedicle in ovariectomy has passed through many varied phases. In 1842 Charles Clay ligatured the pedicle and brought the ligature through the lower end of the abdominal wound, partly to act as a drain, but more especially to provide for removal of the ligature when its separation from the pedicle had taken place. In 1861 Tyler Smith ligatured the pedicle and after cutting the ligature short dropped the stump into the abdomen. Next came the clamp in all its forms, then the stitching of the stump of the pedicle to the abdominal wound. After this was the reign of the drainage-tube. At the present time we have reverted to the plan of cutting short the ligature and dropping the stump into the abdomen, only using the drainage-tube in exceptional cases.

When we glance over the vista of operative evolution we encounter two prominent features—the absence of anything like finality and the dominant tendency to revert to the primitive conception. This being so in the past, it is obviously more than probable that change will still follow change; what is orthodoxy to-day is heresy to-morrow. With this thought in our minds let us critically examine side by side the two operations by the vaginal and by the abdominal routes—now resorted to for removal of the cancerous uterus—and endeavour to estimate their relative advantages as regards the difficulty of performance and the duration of the operation, the amount of skilled assistance that is required, the risk of injury to contiguous organs, and the danger of hæmorrhage and of shock.

The difficulty encountered in removing the uterus by the vaginal route is usually not great. In nulliparous or in old women, however, in whom the vagina is narrow, and especially if the vagina is infiltrated with the cancerous deposit, the difficulties are materially increased. The duration of the vaginal operation is much shorter than that by the abdominal route; and the necessity for a number of skilled assistants is less. Greater skill and judgment are required for the removal of the uterus through the abdominal wall; there is more risk of injury to the ureters, to the bladder and other pelvic viscera, and the minute dissection which is needed to separate the new growth from the healthy tissues, especially from the blood-vessels with corresponding risk of hæmorrhage, all contribute to render the abdominal operation a more formidable procedure than the vaginal operation. The frequently excessive duration of the abdominal operation and the depressing effects of the prolonged exposure of the open abdomen (however warm the atmosphere of the room may be) are each and every one adverse factors, to which may be added a greater risk of septic infection. However carefully the operation be performed there is no evidence as yet that the abdominal operation affords less risk of recurrence of the cancer than does the vaginal method. In addition to the ill-effects that are directly due to the prolonged manipulation of the abdominal contents the protracted administration of the anæsthetic is of serious import. It has been found after lengthy periods of chloroform inhalation that death has occurred many hours, and even days, after an operation and that it was difficult to assign a cause for it. In some of these cases post-mortem investigation has revealed extensive fatty changes in the tissues, especially in the heart, due to the prolonged action of the anæsthetic. The inference to be drawn from all this is that when practicable the vaginal operation is distinctly to be preferred to the abdominal method which should be reserved for exceptional cases.

It is not alone in the mode of performing operations that our department of the profession has developed and is developing; evolution is also at work as regards ourselves and our professional status. We spring from the man- and midwife whose function it was to deliver women in labour, and more especially when the labour was unnatural or

difficult. As time went on he undertook the treatment of such uterine troubles as he could compass during, and apart from, the pregnant condition. As knowledge advanced treatment became more active and the man-midwife, now developed into the obstetric physician, enlarged his sphere of action and undertook operative work on women of a more strictly surgical nature until at the present time operative gynaecology, owing to the brilliancy of its results, has caused the obstetric physician to assume more and more the rôle of an operating surgeon with a tendency to recede from obstetrics. This evolution is now receiving official recognition: the title of obstetric physician is being changed in some general hospitals to that of gynaecological surgeon. The natural result will be that just as the general operating surgeon does not practise midwifery, neither in future will the gynaecological surgeon. Indeed, it is not in keeping with the fitness of things that the man who is constantly occupied in surgical work should attend labours. But as there must always be those who are exceptionally qualified to act as obstetricians the primitive usage will be reverted to and place will still be found for the obstetric physician who will be what the name indicates—a specially skilled man-midwife.

Surgery owes much to the gynaecologist who led the way in the performance of abdominal section. It is no small matter that the gynaecologist can justly claim precedence in thus dealing with this all-important region. It was the gynaecologist who showed how the abdominal cavity may be laid open and its contents freely dealt with; how large growths and integral portions of the anatomy may be removed and cysts filled with septic pus may be evacuated, all without rise of temperature or of pulse-rate and with a continuously tranquil peritoneum, that dreaded membrane of the older surgeon. The potentiality having been demonstrated, more and more boldness has been shown until the surgeon now regards an exploratory incision as an ordinary aid to diagnosis. Obviously all this would not have been possible without the antiseptic methods we owe to Lister, which, after passing through a phase of complexity and steam sterilisers, have now resolved themselves into the practice of bacteriological cleanliness of the patient, the hands of the operator, and of the instruments he uses.

Before concluding permit me to direct the attention of the society—and especially of those members who in the future may practise on the lines I have indicated—as pure obstetric physicians—to the immense benefit that would accrue to medical science by the study of an extensive and systematised series of observations of some subjects which are intimately associated with the practice of midwifery. I allude to prenatal diseases, especially those of specific causation and to the diseases of pregnancy such as eclampsia, blood diseases, and chorea. A closer investigation of prenatal diseases would lead to their more general recognition and treatment, which, in my opinion, would tend materially to reduce the birth-rate of the unfit. The study of these diseases would be furthered by the allocation of a few beds for the purpose in all maternity hospitals. In like manner the exceptional opportunities afforded to the gynaecological surgeon might be utilised in the study of cancer from its clinical aspect. By systematised investigation of each case that comes under notice and by massing together the facts obtained so as to facilitate subsequent reference much light might be thrown on this most important subject.

AN EXPERIMENTAL INVESTIGATION OF THE BUDDÉ PROCESS FOR THE PRESERVATION OF MILK.

By R. TANNER HEWLETT, M.D. LOND., M.R.C.P. LOND., D.P.H.,

PROFESSOR OF GENERAL PATHOLOGY AND BACTERIOLOGY IN KING'S COLLEGE, LONDON, AND PHYSICIAN TO THE "DREADNIGHT" SEAMEN'S HOSPITAL, GREENWICH.

THE importance of a pure milk-supply is admitted by all but the difficulty of supervision of farms and dairies and the ignorance of many of their owners, the problem of transit, particularly in the hot weather, the unhygienic condition of the premises of many of the farms and smaller vendors, and, lastly, the universal custom of keeping and delivering milk in open vessels, instead of in closed bottles

(as is the custom in America and the Continent) render it almost impossible to obtain any ordinary milk in a condition which can be regarded as satisfactory, much less as safe. It is largely the insanitary conditions and methods which exist at the farms that have rendered the extensive use of preservatives necessary (I use the term advisedly). The initial contamination of the milk is such that in hot weather many millions of bacteria per cubic centimetre may develop in a few hours, and within 24 hours much of the milk delivered in London would, I believe, be unusable but for the addition of preservatives. I hope this will not be construed into meaning that I advise the addition of preservatives; I do believe, however, that under present conditions the moderate addition of preservatives is less dangerous than the use of a semi-patrid milk—it is the lesser of two evils.

Four conditions would much tend to mitigate the evil and do away with the necessity for preservatives. These are (1) strict sanitary measures in dealing with the milk at the dairy—i.e., in the milking, &c.; (2) the immediate chilling of all milk after milking; (3) the provision of refrigerator vans for transit; and (4) the sending of milk in closed bottles. These conditions, however, can only be obtained by a combination between the farmers in a district—that is to say, by coöperation. The initial expense of refrigerators, bottles, &c., is too great for the smaller farmers to incur and it is only by pressure brought by a large and united clientele on the railway companies that proper refrigerator vans will be provided and a reduction in freight for bottles (which is now much too high) will be obtained. However satisfactory the conditions may become at the farm one mode of treatment only will prevent the chance contamination of milk with the viruses of tubercle, typhoid fever, diphtheria, scarlet fever, &c., and that is some form of sterilisation. Treatment by heat, either in the direction of complete sterilisation or by pasteurisation, has been extensively used. The objection to sterilisation is that to be complete a temperature above 100° C. is necessary and this produces a marked flavour and undoubtedly diminishes the nutritive and digestive qualities of the milk. To pasteurisation, which consists in heating the milk to from 68° to 70° C., the same objection cannot be made; all non-spore disease germs are destroyed, the flavour is less altered, and the nutritive qualities are less diminished. But pasteurised milk is by no means sterile and its keeping qualities are not greatly prolonged unless the process is followed by efficient chilling. I am also informed that there is a considerable tendency nowadays to run the milk rapidly through the pasteurising apparatus instead of allowing the milk to remain at the proper pasteurising temperature for 20 minutes or so, as should properly be done. Such a procedure would necessarily allow many pathogenic forms to remain alive and would engender a false sense of security.

My attention was recently directed to the Buddé process of treating milk, invented and patented by a Danish engineer, Mr. Buddé, and now being applied extensively and on a commercial basis in Denmark and Sweden. During the summer of 1905 17 creameries or coöperative dairies in these two countries have each installed a plant for "Buddéising" and bottling milk. The principle of this process is as follows. The milk is obtained in as clean a condition as possible, and if it has to be kept for any time before treatment it is efficiently chilled, but usually it is treated soon after milking. A proper proportion of peroxide of hydrogen is added to the milk and the mixture is heated to from 51° to 52° C. for at least three hours. A temperature below 48° C. is not efficient and one above 55° C. should be avoided as this tends to induce changes in the milk. With the aid of the heating the hydrogen peroxide is completely decomposed into water and oxygen by an enzyme (catalase) present in the milk, and the oxygen at the moment of liberation being in a nascent condition acts as an efficient germicide. At the end of the process the whole of the hydrogen peroxide should have been decomposed, provided the right proportion has been added, so that no antiseptic remains, a small but inappreciable addition of water has been made to the milk, and the majority of the micro-organisms have been destroyed. The amount of hydrogen peroxide required to obtain this result is about 15 cubic centimetres of a 3 per cent. solution per litre of milk, so that the quantity of water added to the milk amounts to about 1.5 per cent., which, on a basis of 3 per cent. of fat, would reduce the percentage of fat to 2.85 in the treated milk, a reduction in the percentage of fat of about

0.05, an amount which may be regarded as negligible. The milk is treated in bulk and immediately bottled with suitable precautions and supplied to the public in the bottles, a fact which alone should commend it. The milk so treated is practically unaltered in appearance and flavour, the cream rises as usual, all ordinary non-sporing pathogenic germs are destroyed, and the milk will keep sweet for at least eight or ten days in hot weather.

The capacity of the natural milk to decompose hydrogen peroxide varies, presumably on account of variations in the catalase content. With some of the continental milk less than 15 cubic centimetres of the 3 per cent. peroxide can be decomposed and it is necessary in such cases to add something, e.g., yeast enzymes, which will decompose the excess of peroxide and render the treated product free from this agent. English milk, however, will decompose on an average 17 cubic centimetres of the peroxide per litre, so that there would be no need in this country to make any such addition; the milk itself would completely decompose the requisite quantity of hydrogen peroxide. Even supposing that a small amount of the peroxide did remain undecomposed it could hardly be in any way deleterious; the amount would be infinitesimal. I believe that small quantities are quite non-poisonous and non-deleterious and in the stomach any excess would immediately be decomposed. The enzyme "catalase" has been described by O. Loew¹ and the interaction between various enzymes and hydrogen peroxide has been investigated by Vanderwilde, Waele, and Sugg.²

An important consideration is whether the Budde process alters the nutritive qualities of the milk. Of this I have no personal experience, but Lindman³ states as the result of an extensive use of the "Buddeised" milk in cases of diarrhoea and digestive disturbance that it can be used with the greatest benefit in these conditions and that the nutritive qualities are unimpaired for infant feeding.

I may now give in detail the results of the experiments I have conducted with a view to test the efficiency of the Budde process. The milk was obtained fresh from an Essex farm, chilled at the dairy, and reached the laboratory usually at about 11.30 A.M.—i.e., some four to five hours after milking. It was brought in screw-stoppered bottles of one-litre capacity and on arrival at the laboratory was immediately dealt with. The method of procedure was as follows. Young cultures of the various micro-organisms on solid media were used; these were emulsified in sterile tap-water and the suspensions were allowed to stand for a quarter of an hour, so that the larger particles might settle. The milk in the bottles was emptied into clean glass flasks and from four to five cubic centimetres of the thick suspension of the micro-organism to be tested were added, and the whole was thoroughly mixed; the mixture was then returned to the bottles through a sterile glass funnel. The requisite amount of the peroxide (at the rate of 15 cubic centimetres of a 3 per cent. solution per litre) was next added, the bottles were closed, the contents were thoroughly mixed, and the bottles were wholly immersed in a water-bath kept at 52° to 53° C. Sufficient time was allowed for the contents of the bottles to attain a temperature of 51° to 52° C., and the heating was continued for a further period of from three to three and a half hours after this. Plates and cultures were made from the milk with the added micro-organisms before and after treatment so that the efficiency of the process could be ascertained. The preliminary mixing of the cultures and milk in flasks (and not in the bottles) was to avoid the chance of any of the micro-organisms becoming deposited in the thread of the screw in the mouth of the bottles, where the organisms might have been unacted upon by the peroxide, and at the end of the process might have contaminated the bulk of the milk and so have vitiated the results. Several tests were made to ascertain the effect of the heating alone—i.e., to some of the bottles no peroxide was added—but otherwise they were treated in the same manner as those to which the peroxide was added. Similarly, in other cases the milk without added micro-organisms was treated and tested. In all cases a much larger quantity of the infected milk was added to the test cultures, &c., after treatment than was used for the control cultures, &c., before treatment, and in nearly all cases each

experiment was in duplicate or triplicate—i.e., two or three bottles were treated and tested.

The following is a type of the method of experimentation adopted:—

Experiment VIII.—Bacillus typhosus (agar cultures). Sept. 6th, 1905. The test cultures were made on Conradi plates.

A. Controls before treatment.

Bottle 1. 1 loop (Conradi plate) = several typhoid colonies.
" 2. 1 " " " = a few typhoid colonies.
" 3. 1 " " " = " " "

B. After treatment.

Bottle 1 a. 0.1 c.c. (Conradi plate) = not a single colony.
b. 0.1 c.c. (" ") = " " " "
Bottle 2 a. 0.1 c.c. (Conradi plate) = not a single colony.
b. 0.1 c.c. (" ") = " " " "

Bottle 3 (heated, but no peroxide added).

a. 0.1 c.c. (Conradi plate) = number of typhoid colonies.
b. 0.1 c.c. (" ") = " " "

Experiment XIV. Bacillus tuberculosis.—As I was unable to obtain natural tuberculous milk the milk was infected in two ways and then treated. One method was to dry some sputum rich in tubercle bacilli in vacuo over sulphuric acid, to grind up the dry residue with water, so as to form a thin suspension, which was strained through muslin and added to the milk. The other was to make a suspension of a glyceric agar culture of a virulent bovine strain and add to the milk. The Guinea-pig test was alone employed.

Sputum suspension (Sept. 5th, 1905).

A. Control, before Treatment.

Guinea-pig 63 (1 c.c. injected). Killed Dec. 6th, 1905. Caseous glands and tuberculous nodules in the spleen and liver.

B. After Treatment.

Guinea-pig 32 (2 c.c. injected). Killed Dec. 5th, 1905. No trace of tubercle.

Experiment XV., culture suspension (Sept. 5th, 1905).

A. Controls, before Treatment.

a. Guinea-pig 62 (1 c.c. injected). Died Sept. 29th, 1905. Tuberculous nodules in kidneys, liver, and peritoneum.

b. Guinea-pig 55 (1 c.c. injected). Died Nov. 28th, 1905. Tuberculous nodules in spleen, liver, and lungs. Inguinal glands large and caseating.

B. After Treatment.

Guinea-pig 60 (2 c.c. injected). Killed Dec. 5th. No trace of tubercle.

Experiment XVI. Sputum suspension. (Sept. 6th, 1905.)

A. Control, before Treatment.

Bottle 1. Guinea-pig 57 (1 c.c. injected). Killed Nov. 14th, 1905. Tuberculous glands and spleen.

B. After Treatment.

Bottle 1. Guinea-pig 45 (2 c.c. injected). Killed Dec. 5th, 1905. No trace of tubercle.

A. Control, before Treatment.

Bottle 2. Guinea-pig 20 (2 c.c. injected). Died Sept. 23th, 1905. Tuberculous nodules in mesentery.

B. After Treatment.

Bottle 2. Guinea-pig 56 (2 c.c. injected). Killed Dec. 5th, 1905. No trace of tubercle.

Experiments XIV., XV., and XVI. conclusively prove that the Budde process destroys the tubercle bacillus in milk.

In all, two experiments were performed with the bacillus diphtheriae, two with the bacillus acid lactici, three with the bacillus coli, two with the bacillus typhosus, one with a paratyphoid bacillus, one with the bacillus dysenteriae, one with the cholera vibrio, one with the micrococcus pyogenes aureus, three with the bacillus tuberculosis, three with the bacillus anthracis (sporing), one each with the bacillus subtilis and bacillus mycoides (both sporing), two with the penicillium glaucum, and several to ascertain the reduction effected in numbers of the natural flora of milk by the treatment. In the treated milk a progressive increase in the number of organisms occurs as the milk is kept, but even after ten days the number is four-fifths less than in the original milk before treatment. On two occasions the acidity of the milk before and after treatment was determined by titrating with $\frac{N}{10}$ caustic soda and phenolphthalein

and was found to be unaltered. Several samples were tested (with starch and potassium iodide) after the treatment for the presence of a residuum of hydrogen peroxide but none was detected. The treatment was not found to alter in any way the colour, odour, taste, and appearance of the milk, and the cream rises in a normal manner after the treatment. Samples were tasted by a number of individuals and practically no alteration could be detected as a result of the process.

The conclusions which may be formulated from these experiments and observations are as follows:—
1. All the non-sporing organisms, pathogenic and non-pathogenic, dealt with—viz., the bacillus tuberculosis, the

¹ Bulletin, Department of Agriculture, Washington, 1900.

² Beiträge zur Chemischen Physiologie und Pathologie, Band v., Heft 11 und 12, 1904.

³ A paper read before the Society of Physicians of South Sweden, 1904.

bacillus diphtheriæ, the bacillus acidi lactici, the bacillus typhosus, the bacillus coli, the bacillus dysenterici, a paratyphoid bacillus, the micrococcus pyogenes aureus and the cholera spirillum—are destroyed by the process.

2. Sporing forms—viz., the bacillus anthracis, the penicillium glaucum, the bacillus subtilis, and the bacillus mycoides—are not destroyed by the process although reduced in numbers, the inference being that the vegetative forms are destroyed but the spores are not destroyed.

3. Although the heating *per se* may be efficient in destroying certain non-sporing organisms—e.g., the bacillus diphtheriæ, the bacillus typhosus, and the cholera spirillum—it is not so in all cases. Thus in one experiment the bacillus typhosus and the micrococcus pyogenes aureus survived the heating when no peroxide was added, and under similar conditions the bacillus acidi lactici survived in the two experiments in which this was tested.

4. The same fact is strikingly shown by the effect of "Buddising" on the natural milk—i.e., the milk without added micro-organisms. The reduction in numbers effected by heating alone is far less than with "Buddising."

5. "Buddised" milk is practically indistinguishable from untreated milk in taste, odour, appearance, and in the rising of the cream. No increase in acidity is caused by the treatment.

6. "Buddised" milk will keep perfectly sweet and apparently unaltered in odour, taste, and appearance for at least from eight to ten days in hot weather and for a still longer period in cold weather.

7. In milk obtained in the ordinary way without special precautions the micro-organisms are reduced by the Budd process over 99·9 per cent. In the milk kept at room temperature the small residuum of living micro-organisms multiplies daily and ultimately (after from 12 to 14 days) may cause the milk to go bad.

8. The distribution of the "Buddised" milk in closed bottles is in itself a great improvement on the routine system that obtains in this country of distribution in open vessels.

9. The method excludes all possibility of adulteration of the milk by the vendor before it reaches the consumer.

10. Properly carried out, the whole of the added hydrogen peroxide is decomposed at the end of the process and no trace of it can be detected in the treated milk.

If, as I am informed, the Buddised milk can be produced without necessarily raising the price to the consumer above the ordinary rates, and if the nutritive qualities of Buddised milk are unimpaired, of which there seems to be good evidence, the process appears to have a great future before it for infant, child, and invalid feeding and in the treatment of gastro-intestinal disorders.

In conclusion, I have to thank Mr. Richard Rythen of Broad Street House, London, E.C., who is introducing the process into this country, and Mr. P. Monrad, chemist to the Danish Budd Company, for their assistance in carrying out the above work.

King's College, W.C.

TWO CASES OF LEUKÆMIA TREATED BY THE ROENTGEN RAYS.

By W. IRONSIDE BRUCE, M.D. ABERD.

PHYSICIAN IN CHARGE OF THE ELECTRICAL DEPARTMENT,
CHARING CROSS HOSPITAL.

As the effect of the Roentgen rays on leukæmia is attracting considerable attention at the present time I have thought that some notes of two of my patients suffering from this disease and undergoing this form of treatment may be of interest. Neither case is represented as being complete, as treatment is being continued at the present time.

CASE 1.—The patient, a widow, aged 50 years, had complained for about four months of progressive weakness accompanied by increasing enlargement of the abdomen; she had been losing weight and complained of sleeplessness. She had been previously a very healthy woman but had suffered from malarial fever contracted in Malta (Malta fever?) and also had suffered from sore throats. She had had three children, all of whom were living and healthy. In July, 1905, a diagnosis of leukæmia was made. At this time the patient was very weak and was rapidly getting worse; she complained of great

pain and tenderness over the region of the spleen. Her temperature ranged from 99° to 100° F. in the morning and in the evening from 100° to 103°; she also had occasional rigors. Her spleen was found to be enlarged considerably and reached beyond the middle line; the lower margin could not be felt above the pubes. A blood count taken on July 26th resulted as follows: erythrocytes, 3,047,520 per cubic millimetre; and leucocytes, 400,147 per cubic millimetre, giving a ratio of 1 white to 7·6 red corpuscles. A differential count was not taken. X ray treatment was at once commenced and carried out daily, Sundays excepted. It consisted of ten minutes' exposure of the splenic area, five minutes' exposure of the sternum, and ten minutes' exposure of the knees with a hard tube, taking about two to two and a half milliamperes on the secondary, the tube being about 12 to 15 inches from the skin. The patient had also intramuscular injections of arsenic in full doses; these were discontinued on Sept. 15th.

Blood counts were taken from time to time by independent observers. On August 1st the pain in the region of the spleen was much relieved and the patient slept much better. On Sept. 6th the general health had much improved and the patient declared herself as feeling altogether better. Her temperature was now rarely above 100° in the evening. On the 16th treatment was temporarily discontinued. She went to the country, returning on Oct. 3rd much better in general health. Daily treatment was again resumed. On Nov. 8th treatment was again interrupted for 14 days, being resumed on Nov. 23rd. Treatment daily from Nov. 23rd to Dec. 8th showed a further drop in the number of leucocytes from 72,300 to 32,200 per cubic millimetre. The patient's general condition is still improving, her weight has increased, and the size of the abdomen has diminished. The spleen is much smaller, reaching now to one inch to the left of the umbilicus and one and a half inches above the pubes.

Daily treatment is being continued and the following table illustrates the results of treatment to the end of December, 1905:—

Date.	Ratio of white to red blood corpuscles	Hæmoglobin (per cent.)	Red blood corpuscles (per c. mm.).	White blood corpuscles (per c. mm.).	Polymorpho-nuclear cells (per cent.).	Myelocytes (per cent.).	Other forms (per cent.).

CASE 2.—The patient is a young married woman, aged 23 years. A brief account of her illness and treatment has already been published.¹ The patient had suffered from epistaxis from childhood and had rheumatic fever at the age of 18 years. She was confined on Feb. 17th, 1904, and subsequently had severe post-partum hæmorrhage which was with difficulty stopped. On April 1st she noticed some swelling of the abdomen which continued to increase. She lost flesh rapidly. Menstruation had not reappeared after her confinement. She was admitted into Charing Cross Hospital on Sept. 10th, 1904, under the care of Dr. J. Mitchell Bruce. She was at this time very anæmic in appearance, her tissues were wasted, and the abdomen was greatly increased in size. Her spleen reached downwards to the pubes and extended laterally to within half an inch of the middle line. Its outline was ill defined; it was somewhat tense and on deep pressure was slightly tender. The urine was acid, of specific gravity 1022, and contained no albumin. Auscultation of the heart discovered well-marked aortic and mitral regurgitation. Blood examination showed: red blood corpuscles, 2,300,000 per cubic millimetre; white blood corpuscles, 1,440,000 per cubic millimetre; myelocytes, 34·4 per cent.; polymorphonuclears, 52·5 per cent.; eosinophiles, 6 per

¹ A case of Splenomedullary Leucocythæmia treated with X Rays, Medical Electricity and Radiology, April, 1905.

cent.; nucleated red corpuscles, 6 per cent.; poikilocytosis was fairly marked; hæmoglobin, 34 per cent. The temperature on the average fluctuated between 98° and 100° F. On Oct. 9th the patient was still unable to leave her bed and it was decided to try x ray treatment. Ten minutes' exposures with a hard tube were given over the splenic area only every day until the end of October with an interval of six days' rest after the first nine days of treatment. On Oct. 16th she was able to get up and on the 28th was discharged from hospital. A blood count taken on this date resulted as follows: red blood corpuscles, 3,020,000 per cubic millimetre; white blood corpuscles, 232,000 per cubic millimetre; and hæmoglobin, 37 per cent. Poikilocytosis was much decreased and the proportion of myelocytes was apparently diminished. The spleen was smaller, its lower edge being now one and a half inches less towards the pubes, and its whole outline was better defined.

Since her discharge the patient has been able to walk to the hospital and to attend for treatment as an out-patient. Exposures of ten minutes over the splenic area, sternum, and knees were given each day on alternate weeks. In December menstruation reappeared and was afterwards regular. In January a blood count showed: red blood corpuscles, 3,862,000 per cubic millimetre; white blood corpuscles, 93,000 per cubic millimetre; and hæmoglobin, 44 per cent. In February another count was taken as follows: red blood corpuscles, 4,750,000 per cubic millimetre; white blood corpuscles, 42,200 per cubic millimetre; and hæmoglobin, 46 per cent. The spleen was now much smaller. The patient had increased in weight, was looking better, could walk without fatigue, and could attend to her household duties. From this time on, however, she did not come regularly, her attendances as an out-patient numbered from five to nine each month, and although her general condition appeared to be satisfactory and she could easily perform her duties at home the result of blood examinations show that the improvement reached has not been quite maintained.

The following table shows the differential blood count at various dates:—

Date.	Ratio of white to red blood corpuscles.	Hæmoglobin (per cent.).	Red blood corpuscles (per c.mm.).	White blood corpuscles (per c.mm.).	Polymorpho-nuclear cells (per cent.).	Myelocytes (per cent.).	Other forms (per cent.).

Sept. 9th	1 to 20.6	70.0	4,170,000	202,000	59.3	18.3	22.4

In Case 1 it is to be noted that treatment has been systematic and regular from the beginning and that a steady and progressive rate of improvement is being maintained up to the present time. The general health is better, the spleen is smaller, the temperature is normal, the number of red corpuscles has increased, and the number of leucocytes has fallen from 400,147 to 32,200 per cubic millimetre. The ratio of white to red corpuscles has decreased from 1 to 6.3 to 1 to 141. The proportion of polymorphonuclear cells has risen and the proportion of myelocytes has fallen. Thus in all the characteristic phenomena of the disease there is marked improvement. What the final issue of a case of this type will be it is of course impossible to say, but from a study of the reported cases² there is ground for hope that with increased experience in treating this disease improvements in technique will be followed by considerable improvements in the attained results.

The second case is specially interesting as the patient was at first exceedingly ill and presented all the appearance of an extremely grave case of leukæmia. Whilst treatment was regularly and systematically carried out the improvement was very striking. The bedridden patient was so far restored

to health as to be able to resume control of her domestic duties and to walk to and from the hospital for treatment as an out-patient. The number of leucocytes was reduced from 1,440,000 to 42,200 per cubic millimetre and the ratio of white cells to red from 1 to 1.6 to 1 to 112.5. The number of red corpuscles increased from 2,300,000 to 4,750,000 per cubic millimetre. The patient gained considerably in weight and strength and the size of the spleen diminished. As so frequently happens, however, in hospital practice the patient, being in a condition once more to attend to her work at home, became careless and infrequent in her attendance and her clinical chart showed well how infrequent exposure to the x rays was accompanied by a slow but very perceptible increase in the number of leucocytes and a proportionate decrease in the total of red cells.

Theories as to the source of the curative effect of the x rays in leukæmia are no doubt interesting, but our knowledge of their therapeutic action must be indefinite until something more is known of the etiology of the disease. It is often assumed that the disease is microbic or parasitic and the general opinion at the present time seems to be that the x rays are non-bactericidal. I would like to point out, however, in this connexion that it is possible that the density to the x rays of the glass of which the culture tubes are made has not been sufficiently considered. Lead glasses are very dense to the rays and the glass used in the construction of the Crookes's tubes has to be specially prepared. The x rays therefore may yet be proved to have some bactericidal properties. It is possible also that some or all of the improvement noticed in the treatment of these cases may be due to some other emanations from the Crookes's tube and not to the x rays. Leucocythæmia may be, of course, merely an exaggerated leucocytosis—i.e., an increased formation of leucocytes—or it may be an alteration in the metabolism of cells formed in the ordinary way, which leads to their prolonged life in the body and so to their increased number. The analogy between this disease and sarcoma has been frequently pointed out and the effect of the x rays upon new cell formation of a malignant type is well known. The curative effect of the x rays may be then another instance of their power over the growth of tumour cells.

It has been stated that a too rapid diminution of leucocytes in leukæmia is associated with the production of toxin and the exhibition of high temperature. High temperature has been associated with this disease always and was described long before the introduction of the x ray treatment. The patient in the first case had rigors even before treatment was commenced. In this case also a drop in the number of leucocytes of 40,000 per cubic millimetre was noticed in 11 days without any ill result. My own experience has been that decrease of white cells is invariably accompanied by marked improvement in the general condition of the patient.

The effect of x rays upon pigment is interesting. Case 1 had some pigmentation before treatment by the x rays was commenced. The pigmentation was general and was probably due to arsenic which had been previously given. The patient stated that she was very susceptible to sunburn. After exposure of the spleen to the rays had been carried out for some time the skin over the area became quite negroid in appearance. Some desquamation has taken place since felt has been used and the skin is now much lighter in colour. The great difficulty in this form of treatment is the production of a dermatitis from continuous exposure to the rays. This has the disadvantage of interrupting treatment and is painful and troublesome to the patient. In many of the cases that have been reported it is noticeable that this incident has interfered with the continuance of treatment.³

It is a striking fact that in most of the cases of dermatitis arising in x ray workers the changes in the skin are often limited to the hand and wrist and are not seen beyond the margin of the coat sleeve. This circumstance suggested to my mind the question whether dermatitis could not be eliminated by protecting the skin by layers of substance penetrable by the rays, such as linen, cloth, &c. In Case 2 one thickness of linen (table cloth) was interposed between the tube and the skin. Since this has been done there has been no suggestion of dermatitis and treatment has certainly not been hampered in any way by the use of the linen. In Case 1 four folds of felt, each one-eighth of an inch thick, were interposed at the time that the diminution of white cells from 72,300 to 32,200 per cubic millimetre was noticed in 11 days. In order to allow of

² The X Ray Treatment of Leukæmia, Ledingham and McKerron, THE LANCET, Jan. 14th, 1905, p. 71.

³ Leucocythæmia treated by x rays, Brit. Med. Jour., July 1st, 1905.

larger dosage a heavy anode tube at a distance of 12 inches from the patient was used with a 22-inch coil, the amount of current on primary being 4 amperes, 100 volts. In addition to this, at the end of ten minutes exposure the tube was given as much current as it would stand for one minute. I think the rapid decrease in the white cells just mentioned was due to the extra amount of electric energy used and yet no dermatitis or rise in the body temperature was noticed. On the contrary, there was an extraordinary improvement in the patient's condition generally.

With such large doses of rays as mentioned above, if given in the ordinary way, a very severe dermatitis would undoubtedly ensue very quickly, with possibly severe ulceration of the skin. By my method of protecting the skin I hope to be able to eliminate the burning effects to some extent and at the same time to obtain the fullest benefit from the rays when used as a therapeutic agent. It has been frequently stated that dermatitis is not the product of the x rays but that it is due to the direct action of the high-tension current used to produce the rays. My experience so far strongly supports this contention. The use of protective layers over the skin in these cases tends to illustrate the benefit that may be obtained in a similar way in other diseases in which the Roentgen rays are used and in which the production of a dermatitis is not desired. I hope experiments in this direction will be made and the results noted, as if increased dosage without dermatitis can be obtained a much larger field of usefulness for the rays will be opened up.

The effect of continued irradiation of other organs in relation to the spleen is not as yet accurately known. So far no case has been reported in which any deleterious effect has been noticed. The indefinite manner in which the dosage of the rays is of necessity stated in reporting the above cases is a matter for regret. It has been claimed that a satisfactory method of measuring the radiant energy has been discovered. The amount of rays produced in a Crookes's tubes is, however, dependent upon a number of factors, all of which are not within control. The tubes vary so enormously in efficiency that the quantity of current used, as indicated by a milli-ampere-metre on the secondary of the coil, can give no idea of the amount of rays produced, and it is well known that the penetrative power of the rays alters very considerably during an exposure of any length of time. The measurement of the amount of rays produced and of their penetrative power is a problem which still awaits solution.

Progress in radio-therapy has been so rapid that it is difficult to realise all that has already been accomplished. With such results, however, as are already obtained in leukaemia and in other diseases it is difficult to be anything but optimistic with regard to the future. Increased accuracy of dosage, improved methods of administration, and the elimination of all possible elements of risk to the patient are all points in which we may certainly expect advances to be made, with an almost certain expectation of a still wider field of usefulness for the Roentgen rays.

Weymouth-street, W.

"INTERRUPTED CIRCULATION" AS A THERAPEUTIC AGENT,

WITH ILLUSTRATIVE CASES OF RHEUMATOID ARTHRITIS.¹

BY WILLIAM EWART, M.D. CANTAB., F.R.C.P. LOND.,
SENIOR PHYSICIAN TO, AND JOINT LECTURER ON MEDICINE AT,
ST. GEORGE'S HOSPITAL, ETC.

[AFTER a few preliminary remarks and a brief allusion to his previous paper² under the same title, containing a reference to Harvey Cushing's³ successful use of the tourniquet in a case of Raynaud's disease, and to George Oliver's⁴ pioneer work in the study of tissue lymph in its relation to the circulation, Dr. Ewart commenced the main portion of his paper by describing the technique employed, in the following words:—]

A brief account of the procedure (which is essentially the same as in operations) had better precede the notes of the

cases in which it was applied. In the absence of an Esmarch's tourniquet the simplest substitute is indiarubber tubing of suitable thickness, which is tightened round the limb in single or double loop outside a slight protecting pad. The tube can either be simply drawn tight, both ends of the loop being held, or else coiled over itself to any degree of tightness. As a preliminary the limb is to be rendered anæmic, the patient being in the reclining posture. In many instances the profound anæmia obtained by Esmarch's bandage need not be resorted to, though it is an essential for the best results, but the raised limb must be squeezed empty and kept elevated until after the application of the tourniquet. The relative duration of the constriction will also influence the result and will need to be varied according to the nature of the case. In my hands the shortest has been 30 seconds and the longest from three to five minutes. I have not exceeded six applications at one sitting, with a duration of two minutes each and with intervals of from one to two minutes. Three applications at each sitting may suffice in most cases and two sittings daily may be desirable. It is important to liberate the artery suddenly; and a distinct advantage is gained by lowering the limb into the vertical position, if this can conveniently be done, just before removing the ligature. With sufficient care the risk of any damage from excessive pressure at the seat of ligature is easily avoided. None of the cases hitherto treated have presented the slightest complication referable to the skin, to the vessels, or to the nerves. It need hardly be mentioned that inflamed or tender nerve trunks are an absolute contra-indication just as much as senile and calcified arteries.

THE CASES.

The cases belong to the following groups: (1) Subacute, subpyrexial synovitis, persistent or relapsing, in young subjects of rheumatic tendency; (2) deforming soft puffy nodular arthritis in women, with chronic quiet intra-articular and peri-articular effusions and thickenings; and (3) late massive arthritic thickenings, with articular rigidity or with much stiffness. The treatment was suspended in one case only—that of a stout, florid man of gouty temperament with chronic effusion and synovial thickening of the right knee of eight months' duration. As no visible reduction of the swelling was obtained after three sittings the further application of the method was postponed till other forms of treatment had been given a trial.

[Cases 1, 2, and 3 were those of acute or subacute relapsing rheumatoid arthritis, all in young women. They were treated in June and July, 1905, and all improved while under treatment; since their discharge, however, they have not been seen again.]

CASE 4. *Chronic rheumatoid condition, with acute painful seizures of fixation of joints and muscles.*—The patient, an unmarried female, aged 52 years, had always been healthy, in spite of a gouty tendency, but of late years she had been increasingly liable to acute rheumatoid swellings of the joints and stiffness of the muscles. In the autumn she had quickly recovered from her symptoms during a stay abroad; on returning to London she was seized the same night and rendered quite powerless by stiffness and pains, from which she slowly recovered. Her present attack, the worst she had ever had, began in April, 1905. When she came under treatment in June the very severe pain which she had suffered, apparently from acute neuritis, over the inner aspect of the head of the left tibia was less intense, but there were great aching and tenderness of the swollen left knee and of both hands, the shiny skin of which seemed to be too tight for the enlarged and stiffened phalanges. The temperature was normal or only slightly elevated at times. General treatment by saline laxatives, by colchicum and mercury, and local applications such as in particular of the compound liniment of iodide of potassium, did good. Neither these measures, however, nor massage made so marked and rapid an impression upon the stiffness, the swelling, and the pain as the treatment by interrupted circulation which was applied for upwards of three weeks, and the efficacy of which was demonstrated by limiting its employment to the left arm first, then to both arms, before it was applied to the left thigh. Great relief was obtained in the three limbs, with considerable though not complete loss of swelling. The patient was then sent to Aix to consolidate her recovery.

CASE 5. *Chronic deforming rheumatoid arthritis with effusion and rigidity, but without ankylosis.*—The patient, a married woman, aged 37 years, thin, pale, and nervous, of

¹ A paper written in July, 1905, and read before the Royal Medical and Chirological Society on Jan. 25th, 1906.

² The LANCET, August 13th, 1904, p. 422.

³ Journal of Nervous and Mental Diseases, November, 1902.

⁴ The Oliver-Sharper Lectures on Recent Studies on the Tissue-Lymph Circulation, THE LANCET, April 30th (p. 1175) and May 7th (p. 1272), 1904.

the type known as irritable weakness, but visceraally sound and free from catamenial irregularities, came under treatment in June, 1905. She was then very feeble, stiff, and crippled in her knees and ankles (chiefly on the left side), and in her hands, which presented a wet palm and marked ulnar deflection. The finger-joints of the left hand were abnormally loose, those of the right showing more thickening, particularly the middle and ring fingers, the latter with a distinct float-shaped interphalangeal joint. The wrist-joints were thickened and presented soft synovitic and puffy nodular swellings, with much stiffness, tenderness, and limitation of movement. The patient's expression and attitude were those of helplessness and distress. This condition was the climax of progressive symptoms of four and a half years' duration. The first symptoms after a wetting followed by a prolonged chill in church had set in suddenly in January, 1901, with painful swelling, numbness, and stiffness of both hands, and with severe pains over the whole body which kept her in bed for 14 days. From that date onwards she was never free in some form or other from rheumatic pains or stiffness. She continued to attend to her avocations, often, however, with considerable difficulty; and the effort told severely upon her nervous system, which was naturally delicate, until she lapsed, in 1904, into a condition analogous to neurasthenia, for which she was treated in November, 1904, with hot sulphur baths and ferruginous waters without much or any benefit, and she seems to have then suffered from increased weakness and loss of flesh. The view was taken at that time and since that the arthritic condition was of neurotic derivation and under neuropathic influence. In September, 1901, the recurring painful red and shiny swellings of the right hand had been diagnosed as "rheumatic erythema." The same diagnosis was also given when she was seen in October, 1902. In the interval she had been confined, in May, 1902, of her second child, and had undergone much fatigue. Her first pregnancy, 12 years ago, had been marked by the onset of dental decay, which eventuated in the extraction of seven teeth from the upper jaw and of four molars from the lower jaw at a comparatively recent date. For the last 14 years her residence had been on high ground, where the air was bleak and the water was chalky. Her feet began to suffer during a stay in Africa in 1904, and walking became very difficult owing to the pain, stiffness, and swelling which seemed to affect the whole foot as well as the joint of the great toe. Her condition since then had oscillated without any permanent improvement. Although she was better at the end of the winter spent in the Riviera, the cold wet weather which she encountered on her return determined a severe recrudescence. The knees, particularly the left one, became swollen and very painful and the feet also swelled. The left knee had remained much swollen as a whole and fixed but particularly tender and puffy over the inner aspect of the head of the tibia. The right knee was almost normal in size and movement.

The treatment was directed, as in Case 6, to the husbanding of the general strength and to a general hygiene of the skin, muscles, and viscera, with fairly good results. After a period of rest in bed and of massage, which was of service for the general health, the treatment by interrupted circulation was applied to the right arm first as this was the worse affected. The effect upon the puffy swellings was decided and rapid. They disappeared, as in the cases of subacute rheumatism. After a few days the left arm was also submitted to daily treatment with similar results. The treatment was kept up steadily, and is still kept up, with a view to influence if possible the thickening around the bones. Not only the patient herself but all those best able to judge (including the husband after an absence of three weeks) were agreed that the size of the wrists and of the float-shaped knuckles was perceptibly reduced and the freedom of movement was greatly increased. The left knee, although getting all the advantage that general treatment, local applications, and rubbing could confer, had remained almost as greatly swollen as before, very tender, painful on attempted movement, and incapable of complete extension. The interrupted circulation treatment was at last resorted to three weeks before the date of this report and is still being applied. The progress made during that interval has been great, the patient noticing first a relief and subsequently a disappearance of the pain and tenderness, whilst to onlookers the diminution in the general swelling and the return to a more natural configuration and to greater mobility are quite obvious. As a result of these gains (within seven weeks),

for which the other instalments of treatment are also doubtless, in great measure responsible, the patient has largely recovered from her depression and from her almost melancholic frame of mind and is looking forward to continued progress towards recovery.

CASE 6. Osteo-arthritis with fixation.—The patient, a female, aged 56 years, married, was admitted into St. George's Hospital on June 14th, 1905, in a crippled condition, not having been able to walk (or latterly to stand) without assistance for 18 months past owing to fixation of the knees in a semiflexed condition and to much limitation in the movement of the ankles, and being moreover disabled in the upper limbs by complete fixation of the right elbow and partial loss of movement in the left elbow and by complete fixation of both wrists. Her mother had suffered from rheumatism. She herself had never had rheumatic fever or any serious illness and was fairly healthy-looking for her years. The menopause had occurred at the age of 53. For the last 12 to 14 years the joints had gradually swelled and afterwards become stiff, without pain except on movement; the first joints to be affected were the metacarpophalangeal joint of the index finger and the metatarsophalangeal joint of the great toe on both sides, all at one time. She had been under treatment during nearly the whole period without improvement. On examination no evidence was found of any visceral disease. There were no teeth in the upper jaw and few in the lower. The temperature was normal; the pulse-rate was 96 and the respiratory-rate was 24. The first, second, third, and fifth metacarpophalangeal joints of both hands were swollen, with lipping of the cartilages and grating. The proximal and middle phalanges of the fourth and fifth digits and their joints were swollen. There were ulnar deviation and much limitation of movement of the fingers. The right thumb was rigidly fixed at its proximal joint. There was much wasting of the interossei and of the muscles of both arms. Both knees were enlarged, chiefly the left, and grated on any attempt at forcible extension. The first metatarsophalangeal joints on both sides were swollen, the ankles and tarsal regions were swollen and somewhat rigid, and there was some fibular deviation. The hips and shoulders were comparatively free within the smaller range of movement and the spine, neck, head, and jaw were quite free. The patient could thus be placed in the sitting as well as in the recumbent posture, but in both positions was otherwise helpless.

The treatment included, besides cutaneous hygiene and laxatives, full doses of the hypophosphites and of the glycerophosphates of calcium, iron, and sodium, two ounces of olive oil and half an ounce of whisky every night, a full and suitable diet, massage for the muscles and passive movements of the moveable joints, extension of the knees by weight and of the elbows by elastic traction (to facilitate which my house physician, Mr. V. Hetherington, constructed a convenient apparatus), continued flexor elastic traction for the wrists and the encouragement of active movement, which had previously been limited to a feeble waving of the fingers and to movements of the head and shoulders. The "interrupted circulation" treatment was first applied to the right arm only, as this was the worst ankylosed—namely, one sitting every other day with three "turns" of two and a half minutes' duration. But complete anaesthesia of the limb could never be obtained and the forcible manipulation of the rigid joints during the anaemia—one of the chief features of the treatment—could only be applied very gently on a small scale. Nevertheless, distinct improvement was secured after three sittings, and on June 30th slight mobility had been restored to the rigid wrist and elbow. The treatment was later applied to both arms with daily sittings, and finally to the left thigh. Previously, however, Sir William H. Bennett, after forcible treatment under an anaesthetic (on July 18th), had expressed an opinion that the left knee would never be perfectly straight. Most of the joints were moved that day with much creaking and grating and both wrists were again moved under gas on July 28th. But on both occasions the advantage gained seemed to be lost again during the several days' rest obtained by the surgical interference. Meanwhile the general strength and condition continued to improve and on August 9th the patient was able to stand and a few days later to walk as far as the lavatory. Daily systematic treatment of the arms and of the left leg was applied more regularly and efficiently after August 15th with progressive improvement. But before

that day the patient herself was conscious of the diminution in the size of the heavy wrists as well as of an increased mobility of the joints. The left knee also was now perceptibly less massive. Further progress will be reported later.

THE IMMEDIATE EFFECTS OF THE APPLICATION.

In each of the three stages of the procedure we have to keep separate account of the objective as well as of the subjective effects.

1. *The application of the ligature (with emptied veins)* gives rise to the familiar appearances well known to surgeons. The proof that the ligature has been effectively applied is the continued pallor of the limb and the falling of the superficial veins to fill again. As regards subjective effects, there is no pain but only a sensation of pressure at the seat of the ligature, provided no accidental pinching of the skin between turns of the tubing has occurred, and this, of course, should be carefully avoided. No immediate change in sensation is usually experienced below the ligature.

2. *The period of anaemia*—In most cases no change is perceptible in the appearances beyond a steady increase in the pallor of the skin during the first few seconds. In rheumatoid cases the softer puffy synovial and periarthritic swellings may sometimes be actually seen to have subsided after a minute or two, though some of the swelling may afterwards return when the ligature is removed.

The subjective effects vary. In some individuals there is distinct numbness rapidly passing into anaesthesia. In others the numbness and loss of sensation are delayed or the fingers or toes may retain almost unimpaired sensation throughout the short period of artificial anaemia. In one particular all patients agree. The painful or tender joints are made easier. Pain and tenderness may even entirely disappear. At the same time there is a feeling of recovery if some degree of power for active movement; and when the stiffness is not due to any firm adhesions patients will sometimes spontaneously test the joints by active movements. On the other hand, no painful or discomforting sensations have ever been complained of even during the longest sittings employed (upwards of four minutes).

3. *The removal of the ligature* is followed by a visible bright blush of the skin and nails. Never absolutely immediate this occurrence is preceded by an interval which varies in different subjects and is also apt to vary at different sittings in the same subject. This variability has its clinical importance as probably pointing to differences and variations in the function of the vaso-motor mechanisms. It is also worth mentioning as an instance among the many speculations and studies which are opened up by this method. Together with the blush there also occurs the objective symptom of increased local heat. And there may be a slight visible return in some of the soft parts of the fulness which had disappeared, as, for instance, at the back of the hands, in the interosseous spaces, and about the wrist.

Subjectively, the return of the circulation is always grateful to the patients. They usually dwell upon the pleasant warmth felt to pervade the limb. I have never heard a complaint of any painful sensation, much less of that severe pain which is often associated with the thawing of frost-bitten extremities. It is important to note that the marked relief from pain and tenderness obtained during the period of anaemia is not entirely evanescent, but that the limb remains permanently "easier."

THE CLINICAL RESULTS.

The therapeutical results obtained as regards the arthritic condition have been invariably satisfactory in the cases hitherto treated. Sometimes perceptible even to casual observers they have always been obvious to the patients themselves (see cases). No complications or untoward effects of any kind have been observed. The results may be briefly summarised as follows:

1. The recent puffy swellings in Group I were rapidly amenable to a few applications and in one case to a single application.
2. The inveterate puffy swelling associated with fibrous, cartilaginous, and bony thickenings was sometimes visibly influenced during the application. Its almost complete disappearance after a short series of sittings revealed the articular deformities in their sparer nodular outlines.
3. The periarthritic thickenings were slower to yield but gradually diminished.

4. The thickening of cartilages and of the joint ends of bones may conceivably be found to yield to prolonged treatment. At any rate, some reduction has been observed in the diameter of the float-shaped knuckles and of the swollen wrists and knees in Case 5. But how much of this fining down may have been confined to the periosteum cannot be decided without more searching observation by means of systematic radiography.

5. The great improvement secured with the help of this method in the condition of the articular surfaces in conditions of absolute rigidity from adhesions, both as regards restoration of movement, diminution of cracking or grating, and actual reduction in the size of the joint as a whole, is evidenced in Case 6.

6. In connexion with the latter case attention may also be called to the fact that in limbs so long disused all the tissues must benefit indirectly from the restoration of movement, in addition to any direct advantage conferred upon them by the tourniquet.

GENERAL REMARKS.

The phenomena which have been described in this paper can be easily verified by any observer and they seem to furnish a sufficiently firm basis for clinical action. But their adequate explanation would be very difficult, nay, impossible, at this stage, and, moreover, it would be almost wholly a study in pure physiology. Only few words need therefore be devoted to theory and inference. We seem to be dealing, as previously suggested, essentially with the vascular mechanisms, although the nerves must not be lost sight of. Their terminal fibrils receive a large share of the peripheral vascular effects. They are also immediately concerned in any associated vaso-motor changes and in any loss or depression of sensation. Within the domain of the vascular system an instructive contrast is afforded by Bier's method of "passive congestion" which aims at overcharging the limb with venous blood and with venous plasma by closing the superficial venous outlets by a light ligature exerting but little pressure upon the arteries. The aim in "interrupted circulation" is, on the contrary, to drain the limb of as much venous blood and venous plasma as possible and to furnish it with as fresh an arterial supply as can be obtained. The central facts in Bier's method are the dusky swelling and the vascular turgor. Here the most striking appearances are the anaemia and the subsequent arterial flush; and they represent distinct and, to a certain extent, opposite events which can be broadly defined as "adsorption events" and "stimulation events."

The "adsorption events" are rendered manifest in the group of cases under consideration when the shrinkage which takes place in the synovial effusions or in the softer local swellings chances to be seen or, as is sometimes possible, is verified by measurement during the time of the application of the tourniquet. The inference is that, under the conditions of the experiment, the balance of circulation between the capillaries and the tissues is altered and that, like an imperfectly saturated sponge, the capillary network tends to soak up any surrounding fluid. This view seems to be justified when we watch the capillary circulation in an ulcer of the leg. We then witness a gradual emptying of the capillaries which begins soon after the tourniquet is applied and continues to increase for many seconds, until the red granulating surface is almost quite pale. What has become of the blood? Is its local withdrawal due to a redistribution of the capillary contents of the more superficial and of the deeper districts? Or is it merely due to the blood being sucked up by elastic aspiration into the partly emptied arterial and venous trunks? The slow and gradual establishment of the capillary ischaemia fits in with the view that it may be due to the relaxation of an initial extreme vaso-constrictive spasm, with partial reflux into the re-expanding arteries. And we should not forget that at the same time the empty veins must also claim their accustomed influx. A third explanation which would assume the occurrence, as in Bier's method, of an escape of some of the plasma into the tissues, seems to be inconsistent with some of the appearances as well as with the probabilities.

The "stimulation events."—These may be summed up in two words—"arterial irrigation" and "arterial movement"—which are a welcome sequel to the venous drainage of the limb. Anaemia, it is needless to point out, cannot ever be constructive; any beneficial effect from a sudden withdrawal of the nutrient blood could only be explained

indirectly through its alternative effect upon the nerves, as a nerve shock. It may, nevertheless, as previously suggested, serve a quasi-negative nutritional purpose. Not unlike forced expiration, which expels some oxygen from the alveoli, together with less useful gases, the soaking up of the plasmatic juices makes room for a freshness of supply not otherwise obtainable. Beyond this the local anemia cannot avail to assist nutrition, for its continuance would mean "necrosis" if absolute and "atrophy" if only partial. The vitalising effect which must belong to a full supply of pure arterial blood under full pressure requires no comment, except, perhaps, a reference to the interesting fact that owing to the blood-forming properties of bone marrow this local advantage may be a gain to the general nutrition.

It would occupy too much time to discuss the effects upon the general circulation and upon the general blood pressure which may result from the removal of the tourniquet; they are probably opposite to the consequences of its application. But there is another local influence probably not devoid of importance. In some instances the suddenness of the arterial flush is well marked and suggests that each of the emptied arterioles and capillaries receives as it were a "ramming" charge. Any sudden mechanical effect of this sort is unattainable in the spontaneous variations of the circulation. The impact conveyed to the capillary walls cannot fail to be communicated to the contiguous cells as well as to the fluids in which they are bathed and this "cellular vibration" will be carried wheresoever capillaries extend, even into the inaccessible recesses of bone, in literal realisation of the poet's conception:—

"Ossa tremor." per Ima cucurrit

In conclusion, to meet the possible objection that this method is artificial or unnatural it may be said, not altogether in metaphor, that it is a modification of the familiar treatment by massage. It has just been suggested that interrupted circulation includes an intimate micro-massage of the tissues, but it might almost be added that ordinary massage owes some of its efficacy to the fact that its performance entails a definite though very brief interruption of the circulation at each spot influenced by the pressure of the hand.

I propose to deal in a future communication with the results obtained by systematic treatment in chronic ulcers. The main purpose of this paper, as was stated at its commencement, is to call attention to the principle of "interrupted circulation" as a definite therapeutic agent and to the evidence as to its efficacy, and does not include any attempt to urge its adoption. Much remains to be made out as to the physiological mechanism, as to the advantages and drawbacks, and as to the scope in practical therapeutics which belong to that principle, but above all as to the most practical form under which it may eventually be applied. Upon all these matters I must reserve an opinion until further observation and the help of the experience of other workers shall have matured our conclusions.

ADDENDUM (JANUARY, 1906).

Further Report on Cases.

CASE 4.—This patient has not been seen recently, but she reports that although she has not entirely lost the articular thickening and stiffness she has maintained the advantage which had been secured during her treatment in London, and her after-treatment at Aix-les-Bains, and she is able to follow her avocations.

CASE 5.—In this case, which ceased to be under my observation soon after this paper was written, the tourniquet treatment was resumed after the patient's return home and continued at intervals; but she is unable to report any substantial improvement in the condition of the knee from this treatment or from any of the other remedies which have been resorted to. The local treatment was discontinued because she complained of increased aching supervening in the knee some hours after its application. She writes that she is still unable to walk owing to the painful swelling and stiffness of that joint.

CASE 6 (exhibited).—This patient has remained continuously under observation. There has been marked liability in damp weather to temporary aching and soreness of the joints, with increased stiffness, which have needed special relief by medication. Nevertheless, she has lost none of the ground which she had gained and has continued to

improve in general health and in capacity for movement. She is no longer a cripple, walks rather stiffly, but without crutch or stick, and "she can do everything for herself." But the knees are not yet straight and the right elbow has only a limited range of movement, apparently owing to the obstruction of a bony outgrowth. Comparatively little movement has been regained in the wrists. These joints are smaller and are slowly improving, but their tendency to become fixed if strong passive movement should fail to be applied day by day has not yet been overcome. The mobility of the fingers continues to improve, greatly owing to the patient's own persevering exertions, the beneficial effect of which has doubtless had a considerable share in the benefit which she has secured during her prolonged stay in the hospital.

[As additional cases there were shown two cases of acute gonorrhoeal arthritis and one of acute sprain, also a case of subacute and one of chronic rheumatoid arthritis, in which manifest benefit was derived from the application of the tourniquet.]

CONCLUDING REMARKS.

Further observation in the cases narrated and in others confirms the estimate taken in this paper of the efficacy of the method in reducing the swelling and the pain associated with the intra-articular effusion of synovial fluid or the peri-articular effusion of lymph. The immediate relief afforded in the cases of acute arthritis, whether rheumatic or gonorrhoeal, and of sprain in which it has been tried, is equally striking. But in joints chronically thickened or fixed the improvement reported has not hitherto resulted in any complete cure.

Ourzon street, W.

SOME EXPERIMENTS IN HYPNOSIS.

By EDWIN ASH, M.D., B.S. LOND.,

RESIDENT ANAESTHETIST, LATE HOUSE PHYSICIAN, TO ST. MARK'S HOSPITAL, PADDOINGTON, W.

(With a Brief Account of a Demonstration given before the East Sussex Medical-Chirurgical Society on Dec. 19th, 1905.)

CONSIDERING hypnotism from the point of view of the unbiased inquirer it must be admitted that he is justified at first in feeling somewhat sceptical about the whole matter. The fact that the term "hypnosis" implies either sleep or some condition resembling sleep is likely to be a source of difficulty to the unpractised operator. For although the stages of hypnosis have been very variously described, yet there is a general opinion expressed that an early stage of wakefulness occurs followed by a later condition of sleep of varying depth. One reads that in the early stages the subject is fully aware of everything that is taking place about him, and, indeed, beyond some feeling of drowsiness his condition in no way differs from the normal. Even in a comparatively deep stage of hypnosis he may be quite conscious and subsequently retain a perfect recollection of all that has occurred during the experiment. Thus far it is very difficult to understand in what this "hypnosis" consists. The fact that a person feels some rigidity of his eyelids or even temporary inability to lift them when told he cannot do so may only imply that slight confusion of muscular action which can be produced in almost anybody by very suddenly telling him to put into action some particular group of muscles. Even when actual rigidity (catalepsy) of a limb results from suggestion in the early stages the inexperienced operator cannot feel confident that he is not being deceived by the willingness of his subject or even by the subject's self-deception. It was just this difficulty with which I was confronted when first attempting to produce the phenomena of hypnosis. Indeed, it is a difficulty which always appears when the matter is discussed by the inexperienced. So much so that experiments may have to be discontinued through want of confidence in one's subjects as happened in my own case some time ago. However, after a careful study of the literature dealing with hypnotism, I again determined to carry out a series of experiments which may be of interest to early students of hypnosis as exemplifying the difficulties which at once beset the path of the worker in this field of

psychology and showing how they were cleared away in one particular instance. These experiments were conducted at the East Sussex Hospital, Hastings, the patients being porters and patients of that institution. Numerous experiments were made with each subject, all observed phenomena being recorded at the time. I give notes of representative results obtained in each instance.

The method used at first was fixed gazing at a small polished disc set in the centre of a larger disc of ebony. But it was soon found that by diverting the subject's attention to one hand which I slowly moved from the height of about 18 inches from the forehead down to the level of his eyes and then rapidly past them hypnosis was as readily produced in susceptible people. Sometimes the condition could be better induced in the first instance by placing the whole hand firmly on the head and vigorously pressing the centre of the forehead with my thumb, the subject being seated in a comfortable chair with a head-rest.

Experiments with Subject 1.

H. S., a porter, formerly a soldier, aged 29 years. After several unsuccessful attempts to produce rigidity of the eyelids by pressing with the thumb on the centre of the forehead it was suddenly found that hypnosis had been induced and he was now unable to open his eyes against my command. Rigidity was then readily produced in the arms and the mouth was held firmly open and fixed when appropriate suggestions were given. These results were obtained several times and in none of the experiments did he lose consciousness, being afterwards fully aware of all that had occurred. He described an unaccountable feeling of "stiffness" and inability to move certain muscles when rigidity was suggested. This is evidently the condition of "catalepsy" described by all writers on hypnosis and can be most rapidly induced by directing the subject's attention to any part by gently stroking it. I also found that I got somewhat better results by now using Braid's method of fixed gazing. And as the hypnosis became deeper at each attempt I took careful notes of a series of prolonged experiments, as follows:—

Experiment 1.—The subject went into a light sleep but seemed to be quite out of touch with me. When roused he said that he had been dreaming about his wife and child. He readily again went into a sort of trance condition but nothing further could be done with him. He did not move out of his chair or speak when told to do so. He was awakened readily.

Experiment 2.—This was carried out in the presence of several witnesses. The man was very nervous and had some difficulty in concentrating his attention. Eventually he went to sleep and it was suggested that he was now in my sitting-room cooling the fire. He awakened when told to open his eyes. He said he had been dreaming that he was in my sitting-room reclining in an armchair in front of the fire.

Experiment 3.—He closed his eyes after gazing at the disc for about 60 seconds. I then told him to sleep more deeply and yet more deeply, repeating the suggestions several times. He was then allowed to rest quietly for a few minutes and was then told that when he opened his eyes he would find himself in the entrance-hall checking the admission of visitors (this formed part of his usual work). He opened his eyes when so told and on being questioned said he was in the hall; he seemed very confused and I could get no clear idea of his impressions. He was then given a copy of the Royal Magazine and told it was the patients' admission-book. He agreed that it was and I told him to look up the last entry he had made in it. He said it was the name of a patient. (I subsequently ascertained that the name which he gave was correct.) I pinched his skin and he did not flinch. He would not move about when told so to do but relapsed into a deeper sleep. I had to rouse him by shaking and shouting at him but he remained in a very confused state for about a quarter of an hour with drooping eyelids and tendency to sleep again. He complained of great coldness of the skin. I then told him that in future he would at once awaken when I either blew in his face or clapped my hands. He had completely recovered himself by the end of half an hour.

Experiment 4.—On the next day he seemed somewhat nervous and the first attempt failed, so I told him to look steadily at my right hand and in a few seconds his eyes became heavy. I then said, "Now your eyes are heavy." He replied, "Not heavy enough yet, sir." So I let him gaze a little while longer, when he let his eyes close. This closure

was evidently hastened by a pass made in front of his eyes. I then said, "Now sleep more deeply." He was allowed to rest quietly for about two minutes. It was then suggested that he would find himself in "Casualty" assisting with a case that had just been brought in. He opened his eyes at command and said that he was in the casualty room and that he could see an injured boy lying on the couch, but he would not move from his chair at suggestion that he should assist in moving the boy. He was then told to forget that scene and *analgesia* was suggested. He did not feel the prick of a sharp needle on either hand. His limbs remained fixed in any position I placed them. This is evidently the "flexibilitas cerea" of various authors. He was then given pen and paper and told to write his name and address, which he did very slowly but correctly. I next told him that he would awaken immediately at a given signal, which he did. He complained of intense surface coldness, shivering slightly, but remembered nothing of what had occurred during the experiment.

Subsequent experiments with H. S.—Space will not permit me to give full notes of all the experiments made with this man. I found him more readily amenable to suggestion at each sitting; he was quite fresh when awakened and suffered no after inconvenience. Various hallucinations were readily produced and he would go through various scenes suggested to him. It was found also possible to change his idea of time and of his position in life. On one occasion I told him he was an undertaker and he gave quite a rational explanation of how he had given up his situation as a porter and joined an undertaker in business. Post-hypnotic influence was attempted with great success as shown by the following instances: 1. On one occasion he was told that when he awakened he would go into the main corridor and turn out the electric light. It was about 9.15 p.m. When roused he had no memory of what had been said to him but he followed me through the main corridor where I left him. Watching him from a distance I observed him standing for some minutes looking first at the electric light and then at the clock. He was again very dazed and drowsy. I approached and asked him what the matter was and he replied that he had just had a very curious impulse to switch off the light. He said that it was somewhat extraordinary as it was not his duty ever to turn out that light, and in any case it was an absurdly early hour at which to do so. 2. During another experiment he was told that when awakened he would go into a certain ward, ask for pencil and paper and then write "God save the King." Having roused him I went away and quickly found my way to the ward in question. In a short time H. S. appeared and in a very confused way asked for pencil and paper which were provided for him by the sister in charge who expressed surprise at his request. He became more dazed and on watching him carefully I felt convinced that he had spontaneously passed into a fresh condition of hypnosis. He slowly wrote the words "God save the King" and then at once became his normal self. Taking up the paper he laughed in an amazed way and said, "Well, I seem to be getting jolly loyal." He could in no way explain why he had acted as related. 3. In another case an act was carried out some 14 hours after hypnosis as suggested, the night having intervened. In each instance the man's manner and actions led me to suppose that a fresh hypnosis spontaneously occurred at the suggested time of action, during which he unconsciously performed the act required. My experiments with this subject show that I can in him produce complete analgesia and anaesthesia and induce in him the deepest stages of somnambulism.

Experiments with Subject 2.

W. D., a porter, aged 26 years. Numerous attempts to hypnotise him have been unsuccessful. He gazes unflinchingly and for a long time at the disc without feeling the least drowsiness. By placing my hand on his forehead some stiffness of the eyelids results and on one or two occasions there was distinct difficulty when he opened them against my command. Urgent suggestion makes him somewhat sleepy but on no occasion has any rigidity or stiffness of muscles been produced and he remains, to all intents and purposes, thoroughly awake. He has seen H. S. hypnotised and is a very willing subject but does not seem able to concentrate his thoughts on the point at issue. And although he is most anxious that the looked-for result should occur yet I very much doubt whether even the earliest stage of hypnosis has been induced. Most authors say that drowsiness alone

whole of the preceding experiments he was quite unconscious and had no subsequent recollection of anything that had occurred whilst he was in the hypnotic state, this condition having lasted about 40 minutes.

At the conclusion I was asked again to hypnotise him, which was readily done. It was then suggested by the chairman that as this man had allowed himself to be thus made use of without hope or idea of reward he should be made to take a collection for himself whilst in a condition of hypnosis. This was done and I told him that he had been given a number of counters which he was to put in his pocket. When awakened he had no idea of what had happened and later had an agreeable surprise when told to examine his pockets. The meeting terminated with a discussion of the phenomena observed.

THE ACID EXTRACT OF THE DUODENAL MUCOUS MEMBRANE AS A REMEDY IN DIABETES MELLITUS.

By JOHN HILL ABRAM, M.D. LOND., M.R.C.P. LOND.,
PHYSICIAN TO THE ROYAL INFIRMARY AND LECTURER IN
CLINICAL MEDICINE, UNIVERSITY OF LIVERPOOL.

Dr. R. T. Williamson,¹ writing in 1898, closes his very full account of the treatment of diabetes with the following words: "It will be evident that what is required to enable us to combat the disease successfully is either: (1) some new form of carbohydrate which diabetic patients can assimilate and which can take the place of sugar and starch in the diet; or (2) some internal remedy which will prevent the accumulation of sugar in the blood, a remedy which will enable the system to dispose of the carbohydrates in the normal manner." So far as the first of these requirements is concerned we are in the same position to-day but I am not so sure as to the second.

There is no reasonable doubt that the pancreas plays an important, if not indispensable, part in the assimilation of the carbohydrates. In many cases of diabetes anatomical changes have been found in the pancreas; in others none have been found. However, as was natural, attempts have been made to treat cases with pancreatic extracts. I think I may safely say that they have proved uniformly unsuccessful. We must not forget that the action of a gland may be limited to its living state and that some of the specific changes it then produces cannot be brought about by an extract of the organ. This may be illustrated by the case of the kidney—the living organ can produce the synthesis of hippuric acid from glycocoll and benzoic acid; the dead organ or a renal extract fails completely to do so. We may have in the case of the pancreas a similar position, the living organ has a powerful share in the assimilation of carbohydrates. It has been shown that extracts of pancreas have no glycolytic action. I suggest that it is a function of the living organ, in which case the negative results of pancreatic feeding are explicable.

Now, whilst talking over the subject of diabetes in January, 1905, Professor B. Moore suggested to me that the acid extract of the duodenal mucous membrane might prove of service. I accepted the suggestion readily, for it seemed to me that it afforded some hope of stimulating the living organ. The basis of the suggestion was, of course, the well-known work of Bayliss and Starling who have shown that the contact of hydrochloric acid with the epithelial cells of the duodenum causes in them, the production of a body which is absorbed by the blood stream and carried to the pancreas, there to act as a specific stimulus to secretion. We do not know whether the internal secretion of the pancreas is derived from special cells or from the ordinary cells of the organ. We do know that an active pancreas pours a larger amount of lymph into the efferent vessels and this may include an increase in the internal secretion. Without entering into the battlefield of warring opinions as to the exact methods of their action it may be said that the duodenal mucous membrane, the pancreas, the liver, and the muscles are all concerned in carbohydrate assimilation. It is

difficult in any given case of diabetes to determine which of them may be at fault; moreover they are all under the control of the nervous system, either directly or through the intervention of the blood-vessels. It is impossible therefore to say in any particular case whether the acid extract will prove useful or whether combinations of extracts of these organs may be necessary.

Gilbert and Carnot² have had some results in man with liver extract and O. Cohnheim³ *in vitro* has found marked glycolytic action exerted by a mixture of pancreas and muscle extracts. This, however, has been denied by Claus and Embden.⁴

I shall not enter into further detail on the scientific side of the question, nor do I propose to give full details of my cases. The whole matter is distinctly tentative and I bring it forward in order that a larger number of cases may be tried.

CASE 1.—My first case was that of a man, aged 25 years, who was admitted into my men's ward at the Royal Infirmary on Sept. 14th, 1904. It was a typical case; there were wasting, dry skin, polyuria, excessive thirst, and weakness. The urine contained on an average 3000 grains of sugar and was in quantity from 110 to 120 ounces; it contained acetone and diacetic acid. Codeia was given with no effect. On Nov. 23rd antipyrin was given and in January, 1905, the sugar had fallen to 1000 grains. In January the acid extract of duodenal mucous membrane was given and by the end of May the urine had become quite free from sugar and the polyuria had ceased. The man's sense of well-being was so great that he stopped coming for his medicine. I may say that he had left the hospital at his own request at the end of January. He remained well until August when wasting again set in and in October I again admitted him to the hospital and he died on Dec. 17th from tuberculous caseous pneumonia.

CASE 2.—Meanwhile I had seen, in consultation with Dr. W. Macfie Campbell and Dr. J. Graham Martin, a boy, aged seven years. He had never been a strong lad and in June, 1905, his mother noticed that he was wasting, was paler, languid, always thirsty, and had a huge appetite. Dr. Martin found the urine to measure 70 ounces and to contain 8.3 per cent. sugar = 2685 grains. On July 5th the patient was dieted and put on antipyrin and the acid extract. With slight fluctuations a steady diminution in the polyuria and the glycosuria followed until on August 30th the report of the urine examination was: "Quantity 1180 cubic centimetres; no sugar." Early in October we began to drop the antipyrin day by day, then the acid extract, until on Dec. 2nd the patient was taking no drugs. He is still sugar-free, has gained weight, and is a better colour. I may say that he is still on a fairly strict diet but we propose at the end of January, if the urine remains sugar-free, to see what his carbohydrate limit is.

CASE 3.—The third case that I wish to mention is under the care of Dr. J. Matthews of Blundellsands and as the treatment with acid extract was adopted from hearing of my cases he has given me permission to report it. The patient, a girl, aged nine years, was found to have glycosuria in November, 1905. The urine was of specific gravity 1040 and the sugar was 10 per cent. At first a modified diet with antipyrin and alkalies was given and the sugar fell to 3 per cent. and was steady at this level for three examinations (six days). Acid extract was then given and on Dec. 23rd the urine had become sugar-free. I believe this patient relapsed without any very definite reason but the sugar is again lessening in amount.

I have tried the acid extract in two other cases with a negative result but the duration of treatment was so short that they afford no evidence one way or the other. Fuller details of the cases will be found in the forthcoming number of the new *Bio-Chemical Journal*, edited by Professor B. Moore and Mr. E. Whitley, but I must acknowledge my indebtedness to Mr. Edie for the trouble he has taken in the regular examination of the urine in Cases 2 and 3 and to Dr. Campbell, Dr. Martin, and Dr. Matthews for their kindness in allowing me to report their cases. I do not wish to draw any far-reaching conclusions from these cases but I certainly think that they deserve attention and afford ground for a more extended trial of the extract.

A NEW AND EASY PROCESS OF TRIPLE STAINING FOR CYTOLOGICAL AND HISTOLOGICAL PURPOSES.

BY VICTOR BONNEY, M.S., M.D., B.Sc. LOND.,
F.R.C.S. ENG., M.R.C.P. LOND.,
EMDEN RESEARCH SCHOLAR AND LECTURER OF PRACTICAL OBSTETRICS
AT THE MIDDLESEX HOSPITAL.
(From the Cancer Research Laboratories of the Middlesex Hospital.)

In the course of an investigation upon the nuclear changes characterising certain new growths I was led into various experimental methods of tissue staining in the hope that I might render my work more easy by devising some simple and rapid way by which a sharp colour differentiation between the various constituents of the nucleus, cytoplasm, and intercellular tissues might be obtained. This object I have attained by a process founded on the "triple stain" of Flemming. An account of it has already appeared in Vol. VI. of the Archives of the Middlesex Hospital and I have since that publication further improved upon it. Flemming's "triple stain" is a method well known to workers in the field of cytology. Its original object was to combine in the tissues the stains saffranin, gentian violet, and orange G. in such a way that the chromatic substance of the nucleus should be stained by the gentian violet, the cytoplasm by saffranin, and the intercellular substances by the orange. This at least appears to have been the aim of its originator, but subsequent workers have not attained this ideal and it has fallen into disrepute amongst certain of them. Thus Bolles-Lee describes it as a "clumsy and uncertain method." It is, however, true that other authorities still warmly commend it, although they do not pretend to realise the ideal of a "triple stain" in the sense of giving three distinct colours. Moreover, even when used as a double stain the method is lengthy and uncertain. By the following method a true triple stain can be attained with ease, rapidity, and certainty.

Technique.—1. Fix small pieces of the tissue in acetic alcohol.¹ (The fixatives of Hermann and Flemming may be used if preferred. The older and inferior fixatives such as alcohol, &c., are useless as regards the fine details for which this process was devised, whilst formalin renders it impossible of performance.) 2. Embed, cut, and mount in the usual manner. 3. Stain for one hour in a saturated watery solution of saffranin. 4. Wash in water. 5. Stain for a quarter of an hour in a saturated watery solution of methyl violet. 6. Wash in water and wipe the slide dry except that part occupied by the section. 7. Have ready in a drop-bottle the following solution: to 20 cubic centimetres of acetone add drop by drop a saturated watery solution of orange G. until the flocculent precipitate which slowly appears on shaking is just dissolved in excess of the watery solution; then filter. 8. Flood the slide with this solution. A cloud of colour immediately comes out which obscures the view of the section. 9. Pour this off on to blotting-paper and flood again with the same solution. The colour cloud being much fainter the section can be watched. 10. When the section has attained a rather faint brownish-pink colour, pour off the orange-acetone solution. 11. Wash in acetone for a few seconds. (This should be contained in a small glass jar. Acetone being very volatile, care should be taken that the section does not dry.) 12. Wash in xylol. 13. Transfer to low-power microscope and see if the proper result has been attained. 14. Wash in two fresh changes of xylol. 15. Mount in xylol-balsam.

Result.—All chromatic elements, nucleoli, and certain nuclei, such as those of polymorphonuclear leucocytes, stain a rich violet, chromosomes standing out with peculiar distinctness. The spindle fibres of nuclear mitosis stain a faint pink. The cytoplasm stains a rose pink. The intercellular tissue stains a pale yellow. These effects are best seen if the slide be examined through a deep blue screen.

Notes.—A. The method appears to depend upon a selective

action of the orange-acetone on the saffranin and methyl violet. It displaces both of them from the tissues but removes the saffranin most rapidly from the chromatic elements, whilst it displaces the methyl violet most rapidly from the cytoplasm. B. The most important factor in the process is the orange-acetone solution. If this is allowed to act too long the whole section is stained a uniform yellow. If it has not acted long enough the section is blotchy from methyl violet remaining in the cytoplasmic structures and has a distinct violet tint. If the colours are discharged too rapidly the orange acetone is too strong and should be diluted with acetone. The reagent deteriorates after a time. C. The duration of the exposures to the saffranin and methyl violet may be varied respectively according to the particular tissue under preparation. The periods I have given represent a fair average. If the saffranin has acted too long relatively to the methyl violet all the latter stain will be displaced, the saffranin alone remaining in the chromatic elements, a want of distinctness in these structures resulting. If the methyl violet has acted too long the saffranin is discharged from the cytoplasm before the methyl violet and the preparation is blotchy and indistinct. A very slight degree of practice is sufficient to overcome these difficulties. D. If on examination with the low-power microscope (see above) it is found that not sufficient colour has been discharged the treatment with orange-acetone should be repeated. If, however, too much colour has been discharged the specimen had better be taken back from xylol, through acetone, to water, and the process begun over again.

Devonshire-street, W.

THE IMPORTANCE OF A STRICTLY LIMITED LACTATION.

BY A. DINGWALL FORDYOE, M.D. EDIN.,
F.R.C.P. EDIN.,

PHYSICIAN FOR DISEASES OF CHILDREN, NEW TOWN DISPENSARY,
EDINBURGH, MEDICAL REGISTRAR, ROYAL INFIRMARY,
EDINBURGH.

FOR everyone through whose hands are constantly passing cases of illness in childhood and infancy the question of infant feeding is a matter of primary importance and, consequently, the condition of health of the mother is a subject of the greatest importance and interest. In the study of this question it seemed to me that some interesting light might be thrown on the very complicated subject of the relationship between mother, fetus, and suckling by observations on the concurrence of pregnancy and menstruation with lactation and as a consequence of the results obtained I am led to advance this plea for a more strict limitation of the length of lactation.

My observations were conducted in the case of 100 mothers from whom there were born 405 children (five cases of twins), and of these 400 deliveries there were 374 from which 378 infants survived at least two months. In 259 of these 374 deliveries (69 per cent.) the children were nursed on the breast, wholly or partially, for at least two months; and, therefore, in 259 cases there was a possibility of pregnancy or menstruation occurring during lactation. Of these cases the average duration of suckling was ten months. In six cases the condition as regards the menses was not ascertained, and of the 253 lactations in which this point was determined, in 153 (60 per cent.) there was complete amenorrhoea and in 100 (40 per cent.) menstruation occurred. Of these 100 occasions in which menstruation occurred during lactation the date of the return of menstruation was:—

During the first two months after birth in 27 cases.			
"	third	month	" 7 "
"	fourth	"	" 4 "
"	fifth	"	" 11 "
"	sixth	"	" 15 "
"	seventh	"	" 9 "
"	eighth	"	" 12 "
"	ninth	"	" 7 "
"	tenth	"	" 1 "
"	eleventh	"	" 5 "
"	twelfth	"	" 1 "
"	thirteenth	"	" 1 "

¹ Pure glacial acetic acid 1 part and absolute alcohol 2 parts. Immerse small pieces of tissue not exceeding a 3 mm. cube from 5 to 15 minutes, according to size. Dehydrate rapidly in several changes of absolute alcohol. It is of great importance that the glacial acetic acid should be pure (99 to 100 per cent., freezing point 15° C.) and that the alcohol should be absolute.

From which it is seen that in more than one-fourth, or 27 per cent., of these cases menstruation returned within two months of delivery, and in 92 per cent. of cases within nine months, figures closely agreeing with those of Mlayer who found that in 685 lactations menstruation returned in 25 per cent. of cases within the first six weeks after delivery.

Of the 253 cases of lactation the position of the children in the family and the condition as to amenorrhœa or menstruation during the lactation, with the average duration of lactation for the children of each position, were as follows (Table I.):—

TABLE I.

Position of child.	Number of cases.	Amenorrhœa.	Menstruation.	Average duration of lactation.
1st	71	40	31 (44%)	9 months.
2nd	54	28	26 (48%)	10 "
3rd	44	26	18 (40%)	10½ "
4th	24	15	9 (38%)	11½ "
5th	22	14	8 (36%)	9½ "
6th	15	11	4 (27%)	9½ "
7th	8	7	1 (13%)	12 "
8th	7	5	2 (29%)	9 "
9th	4	3	1 (25%)	9½ "
10th	1	1	0	12 "
11th	1	1	0	12 "
12th	1	1	0	12 "
13th	—	—	—	—
14th	1	1	0	12 months.

From these figures it would appear that menstruation during lactation is decidedly commoner with the early

children than with the later. This, however, might be due to the fact that the earlier children were longer on the breast, but a glance at the last column of the foregoing table shows that with no child is the average duration of lactation shorter than with the first, and, consequently, that the increased frequency of the return of menstruation during lactation in the earlier lactations is not due to the greater length of the lactation period. As regards the date of the return of menstruation in the cases of the different children in the family, Table II. gives these dates and also the percentage frequency of the return under two months after delivery and at the sixth month:—

TABLE II.

Position of child.	Number of cases.	Return of menstruation.													Under 2 months.	At 6th month.
		Within 2nd month.	3rd month.	4th month.	5th month.	6th month.	7th month.	8th month.	9th month.	10th month.	11th month.	12th month.	13th month.	14th month.		
1st	31	11	4	2	2	1	5*	1	1	1	2	1	—	—	35	65
2nd	26	5	2	1	3	3	2	6	3	—	1	—	—	—	19	53
3rd	18	5	—	1	1	3	1	4	2	—	1	—	—	—	28	56
4th	9	2	—	—	2	3	—	1	—	—	—	—	—	1	22	33
5th	8	3	—	—	2	1	1	—	1	—	—	—	—	—	38	75
6th	4	—	—	—	1	2	—	—	—	—	1	—	—	—	0	75
7th	1	—	—	—	—	1	—	—	—	—	—	—	—	—	0	100
8th	2	—	1	—	—	1	—	—	—	—	—	—	—	—	0	100
9th	1	1	—	—	—	—	—	—	—	—	—	—	—	—	100	100

From the above it is seen that in a considerably greater proportion of cases does menstruation return within 4

months in the later children than in the earlier children, and as the average lactation period of the later children was as long as that of the earlier children, it appears that when menstruation occurs in later lactations it occurs early or not at all. Of the 100 mothers examined, 87 suckled a child for two months on at least one occasion, and of these 87 who suckled once or oftener 47 experienced the return of menstruation during lactation; while of the 47, in 26 cases it occurred with every lactation. Menstruation during lactation was thus found to occur in nearly 1 in 2 of the subjects examined and in the great majority of the cases the return of the menses took place within nine months of delivery. That in no single instance was the suckling seriously affected is an important point, and the fact that the return of menstruation is commoner during the earlier than the later lactations would seem to indicate that its return is accelerated in the case of the younger and stronger mothers. This condition, therefore, by no means necessarily serves as a contraindication for the continuation of suckling, and a French author indeed—M. Gillet—goes so far as to recommend as a wet-nurse the woman who menstruates regularly during lactation, as this he considers to be a sign of robust health.

The condition of pregnancy during lactation is, however, a very different matter. Of my 259 cases where this was a possibility it occurred 29 times, and the following table summarises these cases. Here it will be seen that of the 100 mothers in 24 per cent. pregnancy occurred during lactation and in 29 out of 374 conceptions—i.e., 8 per cent. of conceptions, or in 11 per cent. of cases where the infant was reared for at least two months on the breast. Thus in 24 per cent., or nearly 1 in 4 of the mothers, there occurred at some period an overlapping of pregnancy and lactation, and in five cases this occurred twice, and this occurrence took place in 11 per cent. of the lactations.

From Table III. it is seen that the duration of the overlapping of pregnancy and lactation was:—

In 8 cases ... 1 month	In 4 cases ... 5 months
" 7 " ... 2 months	" 2 " ... 6 "
" 4 " ... 3 "	" 1 case ... 9 "
" 3 " ... 4 "	—
Total 29	

and thus that in the majority of cases the period was a comparatively short one. The fetus conceived during lactation was in 14 cases the second member of the family, in eight cases the third, and in seven cases the fourth; and in connexion with later members of a family there was no such occurrence. It therefore certainly appears that this occurrence takes place most frequently in connexion with the earlier children of a family, as might, perhaps, be expected looking to the larger number of early children and the greater frequency of bottle-feeding among the later ones. This would not, however, seem entirely to explain the matter or the entire absence of cases of overlapping among the later children and it may safely be said that this condition of affairs is extremely uncommon. The average duration of lactation of those infants during whose suckling pregnancy occurred was 12 months, while of all the 259 lactations the average duration was ten months. In only two cases did conception occur prior to the sixth month after delivery and the average date of conception was nine months after delivery, while the importance of the lengthened average period of lactation is observed from the fact that no fewer than 12 cases occurred at, or after, the tenth month. These figures largely bear out the statement of McCann that "the greater number of pregnancies during lactation commence after the eighth month."

In 17 cases (59 per cent.) menstruation occurred prior to conception and in 12 cases (41 per cent.) there was no previous menstruation. Remfry, in the course of 900 lactations, found amenorrhœa in 503, or 57 per cent., and menstruation occurred in 338, or 43 per cent., and these figures correspond very closely with my own, which were 60 per cent. with amenorrhœa and 40 per cent. with menstruation. Of the 503 cases with amenorrhœa he found that pregnancy occurred 29 times (6 per cent. of cases) during lactation, while of the 338 cases with menstruation pregnancy occurred in 226 (60 per cent.) during lactation, and he therefore concludes that where menstruation returns during lactation the chances of pregnancy occurring are ten times greater than where there is amenorrhœa. While in my cases it was also found that pregnancy was more common

after the return of menstruation the same marked disproportion between the two classes of cases was not obtained, and thus while in 153 lactations associated with amenorrhœa pregnancy occurred in 12 cases, or 8 per cent., in 100 cases associated with menstruation pregnancy occurred in 17 cases, or 17 per cent., pregnancy consequently occurring rather more than twice as frequently after the return of menstruation as where there was amenorrhœa.

As regards the condition of the children, those in fairly good health have been described as alive and well, while the weakly children have been described as delicate, the sucklings naturally being of greater age than the fetuses and therefore their lives having been exposed to greater dangers. Notwithstanding this it is found that of the 29 sucklings 22 (76 per cent.) were alive and well at the date of examination, while of the 31 fetuses 13 (42 per cent.) only were alive and well at this date. These figures appear to me to be somewhat striking. The works of Prochownick and Noel Paton, in human subjects and guinea-pigs respectively, have conclusively shown the remarkable effect of variations in maternal diet on the embryos, and one might, *a priori*, expect to find the infant of a poor woman, not too fully nourished and for some period, at least, of her pregnancy engaged in the function of lactation, would start life severely handicapped. That this is so my figures show.

Jacobi, many years ago, stated that "lactation and pregnancy are incompatible," but this opinion of the condition would appear to have been anything but universally accepted and in support of the contrary opinion Paquy reports 29 cases of pregnancy occurring during lactation in none of which was any evil effect whatever noticed, and he refers to the well-known condition of affairs among domestic animals, an analogy which appears to me in many respects unsound. That the condition is by no means markedly uncommon has already been pointed out by Robertson and Church and the cause of this is undoubtedly to be found in the widespread belief among the working classes that so long as lactation is continued pregnancy will be avoided—a belief which leads inevitably to the undue protraction of breast-feeding. In such cases the importance of the condition is but ill-recognised from the fact that the suckling probably continues well and thriving, while irrevocable injury is being done to the unseen fetus and consequently the greater need there is of emphasising the dangers of the position.

That the constant reiteration of the command for maternal nursing is as imperative to-day as it ever was goes without saying, but it appears to me indubitable that along with this is the very important obligation of the demand for a strictly limited lactation. My own figures are small in number but very largely agree with, and corroborate, those of former authors, and judging by them I advance this opinion on the following grounds: 1. The concurrence of pregnancy with lactation is comparatively common. 2. Conception is rare within the first six months of lactation and uncommon before the eighth month. 3. Where pregnancy and lactation overlap the fetus is likely to suffer. That every case must be judged on its own merits is a truism, but given fairly average conditions, a strong healthy suckling, and the prospect of intelligent hand feeding the above facts point very strongly to the advantages to be derived from weaning early in the eighth month.

TRADE ADVERTISEMENTS AND "THE LANCET."

The several correspondents who have sent to us a post-card issued by Messrs. Wright, Layman, and Umney containing an advertisement of Wright's Coal-tar Soap, with a reduced fac-simile of the heading of THE LANCET, will kindly note that this unauthorised and unjustifiable use of our title has been dealt with, and the further issue of the offending card has been stopped. In justice to Messrs. Wright, Layman, and Umney, it should be stated that the card was a creation of their advertising agents who have apologised for the offence and have delivered up to us the stock of the fac-simile headings.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF CONGENITAL RIGHT INGUINAL HERNIA CONTAINING A MECKEL'S DIVERTICULUM ADHERENT TO THE APEX OF THE SAC.

By C. B. HOWSE, F.R.C.S. ENG.

A MALE, aged 18 years, was admitted to York County Hospital on Dec. 12th, 1905, for a radical cure of a right inguinal hernia. The hernia had been present from birth. It extended into the scrotum when the patient stood up and formed a swelling of about half the size of the adult fist. On putting the patient on his back the whole swelling was apparently easily reducible with characteristic gurgling. On closer examination, however, a peculiar indistinct mass was felt in the line of the inguinal canal, which gurgled distinctly on rolling it between the thumb and index finger; it had no impulse whatever on coughing and could not be reduced. Mr. F. Shann, under whose care the patient was, kindly gave me permission to operate, and on cutting down and opening the sac I found gut which was bound down by many adhesions to the apex of the sac. The piece of gut was adherent by its blunt apex only. Seeing that there was no mesentery I thought at first it was an infantile cæcum, but on dividing the above-mentioned adhesions and pulling down a couple of feet of gut I found it was a Meckel's diverticulum about two and a half inches long and of about the same diameter as the gut it sprang from. How far along the ileum it arose was not seen as the cæcum was not brought into the wound. A few silk sutures were inserted to cover the raw end of the diverticulum with a peritoneal covering. During the operation distinct peristaltic movements were seen in the diverticulum. The remainder of the operation consisted of Bassini's method of radical cure. The wound healed by first intention and the patient was up on Jan. 5th, 1906.

Meckel's diverticulum occurring, I believe, in only about 2 per cent. of subjects, its presence in a hernial sac must be very rare. I can find no record of its occurrence in this situation and therefore I think the case worthy of publication.

Chiswick, W.

A CASE OF LUMBAR PUNCTURE IN OBSTRUCTED LABOUR.

By FRANCIS FREDERICK JONES, M.R.C.S. ENG.,
L.R.O.P. LOND.

ON Dec. 10th, 1905, I attended a woman in labour with a seven months' fetus. The breech presented and the head was of enormous size. Being convinced that the child was dead I punctured the spinal membranes in the lumbar region with a scalpel. Some cerebro-spinal fluid at once escaped, but the head did not diminish much in size, so I went home to get a perforator. On my return, however, I found that the head was born in consequence of the fluid draining away during my absence. A trocar and cannula would probably have been more suitable than a scalpel for making the puncture.

Twerton-on-Avon, Bath.

CENSURE OF A MIDWIFE—At an inquest on the body of an infant, held at Buckland, Devon, on Jan. 16th, the medical evidence showed that the child was stillborn but that it would probably have lived if a competent person had attended at the birth. The mother had been under the care of a midwife who stated that she had acted as such for 16 years but had no certificate and intended to give up her work. The coroner said that upon her undertaking to do so further proceedings would probably be taken. The jury returned a verdict that the child was stillborn through her attention at birth.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Three Cases of Myoclonus.—"Interrupted Circulation" as a Therapeutic Agent.

A MEETING of this society was held on Jan. 23rd, Sir DYCE DUCKWORTH being in the chair.

Dr. FREDERICK TAYLOR read a paper on Three Cases of Myoclonus. He said that the first patient was a labouring man whom he had seen for the first time 30 years previously. The condition had not materially altered in the last six years. The head was in constant movement in consequence of clonic contractions of the muscles of the neck, and the movements were partly backward jerks and partly lateral movements of a quiet shaking character. Thus the head was moved right, left, and right again, then a pause, then the movement was repeated. The movements were worse when he was standing than when lying down, and they were increased by efforts to follow objects with his eyes. As he stood he swayed a little, both with eyes open and shut. When he walked the gait was ataxic. The ataxia varied and he was often more steady when walking alone than when helped. The ataxia appeared to be due to sudden rising on one or other foot and was less a cerebellar reel than a forward and backward "pitch." Lying in bed he could move the legs more steadily with only a little swaying when they were lifted high. There was a constantly repeated contraction of the lumbar and flank muscles, chiefly of the quadratus lumborum, but also of the lumbar portions of the erector spinæ, latissimus dorsi, and abdominal muscles. These clonic contractions, repeated at the rate of about 100 in the minute, were sufficiently powerful to shake the bed; they no doubt accounted for the slight swing of the lifted legs and largely, if not entirely, for the ataxia of his gait. There were no similar movements in the thighs, legs, buttocks, or in the upper part of the trunk or arms. The muscles were normal in bulk and electrical reactions and the sensory functions were normal. There was no nystagmus. The patient never walked properly, but the movement of his head began when he was aged 21 years. He had never had vomiting or convulsions, but recently he had complained of headache and occasional vomiting. He was in Guy's Hospital for several months in 1903 and was treated with potassium bromide and electricity but without any result. The case appeared to Dr. Taylor to be a form of the condition described in 1881 by Friedreich as paramyoclonus multiplex and more recently by others as myoclonus. The constant condition was the clonic contractions taking place in the lumbar and cervical muscles, and the ataxia, for which the lumbar contractions were responsible. The second case came under Dr. Taylor's notice in October, 1879. The patient was aged 19 years, and four years previously he had suffered from cramps in the right hand which were thought to be writer's spasm. The affection then spread to the muscles of the neck and when Dr. Taylor saw him there was a close resemblance to a case of spasmodic wryneck, with unusual extension to the arm and greater action in the posterior cervical muscles than in the sterno-mastoids. Seven months later he began to have clonic contractions of the muscles of the left loin, chiefly the quadratus lumborum. In 1882 he was still suffering from spasmodic contractions of the sterno-mastoid, posterior cervical muscles, and left flank muscles. The latter constantly drew his left shoulder down to his left ilium and bent him bow-like, a sort of pleurosthotonos. Several years afterwards he was in the same condition. The view originally taken of the case was that it was of the nature of wryneck, with an extension to a new region—wryloin. But as long as the intimate pathology of this condition was unknown it could scarcely be excluded from the very wide group of myoclonus. The third case had been seen recently and it was that of a woman suffering from paraplegia, secondary to the formation of a cancer in the breast which was removed in 1901. From her childhood, however, she has been subject to a tremulous condition of the arms which on careful examination proved to be due to constant clonic contractions of the muscles arising from the internal condyle on each side. The

biceps and triceps were quiet, but a slight shock in the arm due to the above-mentioned contractions could be felt. The pathology of cases called myoclonus was at present obscure. The movements present resemblances to those of chorea, electric chorea, spasmodic wryneck, convulsive tic, and certain movements in hysteria. They were spontaneous, intermittent, sudden, or "lightning-like," single or multiple, but in all cases incoordinated contractions of muscles, or large parts of muscles. Considerable variety was possible in the part of the body affected and the extent of the body involved.

Dr. E. FARQUHAR BUZZARD referred to the indefinite idea which was conveyed by the term "myoclonus" which had been applied to most various forms of muscular spasm. He would apply the term to those cases in which the muscular contractions were of "lightning-like" character but he admitted the difficulty of separating such contractions from other forms of muscular spasm. In considering the pathology of the condition, he said that the contractions might be due to impulses from the central nervous system or to the increased excitability of the muscles. He was inclined to think that too much was attributed to the central nervous system and recently it had been shown by physiologists that there were two contractile substances in muscle: (1) a fibrillar substance, and (2) protoplasmic substance. When the protoplasmic substance was in excess then the slow contraction similar to that seen in Thomsen's disease was obtained, whilst in myoclonus he suggested that an increase of the fibrillar substance might be present and lead to an increased excitability and rapid contracting of muscles.

Dr. O. E. BEVER said that he thought that the second case reported belonged rather to the condition known as spasmodic wryneck than to the class myoclonus. He would use the term myoclonus to indicate sudden muscular contraction of single muscles which could not be thrown into action by will. He thought that such muscular contractions must be of spinal, and not of cortical, origin, for movements were represented in the cortex and not single muscles. With regard to the third case reported, he was of opinion that that was a true case of paramyoclonus.

Dr. F. E. BATTEZ said that he was of opinion that the term myoclonus should not be used for all forms of muscular contraction but that the term should be limited to sudden clonic contraction of single muscles or parts of muscles. He thought that the classification suggested by Lundborg was that which was most suitable under the present conditions of knowledge: (1) myoclonus, using the term as a symptom indicating a form of myospasm characterised by spontaneous and isolated contraction of individual muscles; (2) myoclonus multiplex; and (3) myoclonus epilepsy. In reply to Sir Dyce Duckworth, he said that he would place Dr. Taylor's first case under heading (1) and regard the myoclonus as a symptom occurring in association with a case of spasmodic tic.

Dr. TAYLOR, in reply, said that he fully realised the difficulty of classification and he had regarded his second case as one of spasmodic wryneck until the likeness to his first case seemed to justify it being classed as myoclonus.

Dr. W. EWART then read a paper entitled "Interrupted Circulation" as a Therapeutic Agent" and showed illustrative cases of rheumatoid arthritis. The paper is published in this issue of THE LANCET (p 213).

MEDICAL SOCIETY OF LONDON.

Uncontrollable Vomiting in Pregnancy.—Dilatation of the Cervix Uteri with Bossi's Dilator.

A MEETING of this society was held on Jan. 22nd, Sir LAUDER BRUNTON, the President, being in the chair.

Dr. G. H. A. COMYNS BERKELEY read a paper on Uncontrollable Vomiting in Pregnancy. He commenced by narrating the case of a woman, aged 24 years, who was four and a half months pregnant and in whom it was proposed to induce premature labour on account of uncontrollable vomiting. A few weeks later hæmorrhage set in and abortion took place. At a subsequent pregnancy uncontrollable vomiting again occurred associated with severe pain in the pelvis and lower abdomen, the pulse being unduly rapid (from 110 to 120). Some of the symptoms of intestinal obstruction supervened. The uterus was emptied but the patient died two days later. At the necropsy a Meckel's diverticulum was found which passed through a hole in the mesentery of the small intestine. The Meckel's diverticulum had evidently become

pushed upwards by the enlarging uterus at each of the pregnancies and becoming constricted against the edge of the orifice in the mesentery had given rise to vomiting and, finally, in the last pregnancy had become gangrenous and had resulted in death. Details were then given of 32 other cases in which hyperemesis gravidarum had been diagnosed but in which the vomiting was proved on the death of the patient to be due to some other cause not diagnosed during life. Among these causes were the following: cancer of the pylorus or stomach, tumour of the brain, tuberculous meningitis, epigastric hernia, carcinoma of the liver, latent abscesses in various situations, constriction of the ileum by a band of adhesion, dermoid cyst of the ovary, fixation of the uterus by adhesions, gangrene of the intestine, septic bronchial glands, partially strangulated hernia, ovarian tumour with twisted pedicle, gastric ulcer, malignant disease of the ovary, and old adhesions of the intestines. The symptoms of true hyperemesis gravidarum were next discussed. The vomit occasionally became stercoraceous. The examination of the blood and of the urine might afford a clue to the diagnosis of the cause. The vomiting which was directly due to pregnancy might be neurotic or toxic in origin and the prevailing opinion in the medical profession was that true hyperemesis gravidarum was in most cases toxicæmia and therefore a more exhaustive investigation of the blood and of the urine in such cases might throw considerable light on the subject. The vomiting that was only associated with pregnancy might be reflex or organic in origin. Reflex vomiting was generally connected with some displacement of the uterus or lacerations of the cervix. The organic causes of associated vomiting were very numerous; some were discoverable by careful search but others, like those previously mentioned, were practically undiscoverable during life, but the greatest care should be exercised and the most exhaustive examination should be made. Dr. Berkeley advocated that every endeavour should be made to obtain a post-mortem examination of all cases dying from supposed hyperemesis gravidarum, by which means he thought that the present conception of the disease might be considerably altered. He also suggested that the induction of premature labour in cases of hyperemesis should be carried out much earlier than was usually the custom not only because the chances of recovery would be much greater—since in some of these cases which were left the woman died in spite of the induction and thus the death-rate was abnormally high—but also because, if the vomiting did not cease after the uterus was emptied there would then be time to seek for, and to deal with, some associated cause. In his view the death-rate would be considerably lowered by these means.—Dr. V. BONNEY confirmed the findings at the post-mortem examination on Dr. Berkeley's case. The difficulty of diagnosing such cases must be very great. He referred to a case of hyperemesis gravidarum that he had seen in which nothing could be found at the time. Subsequently there was evidence of there having been an extra-uterine gestation, which resulted in death consequent on its rupture. In another case he had found abscess of the uterine wall.—Dr. G. F. BLACKER referred to the case of a woman, aged 43 years, who was said to be pregnant and who was the subject of uncontrollable vomiting and albuminuria. It was, however, ascertained that she was not pregnant at all; under an anæsthetic a fibroid of the uterus was discovered. He advocated more exhaustive examination of such cases. The toxic cases were most serious; cases of reflex vomiting got well.

Dr. BLACKER read a paper on Dilatation of the Cervix Uteri with Bossi's Dilator. One of the most important questions that the obstetrician had from time to time to answer was what was the best method of rapidly dilating the cervical canal in cases where immediate delivery was indicated in the interests of the mother or of the child. Bossi's method of rapid artificial delivery had now been in use for some 15 years and a sufficient number of cases had been recorded to enable a correct judgment to be formed as to its merits and defects. It was claimed for his method of rapid dilatation of the cervix with a mechanical metal dilator that it was certain and successful even in cases of primiparæ in whom the cervix had undergone no shortening or obliteration and that such dilatation could be carried out with great rapidity. The use of the dilator involved no extra risk of septic infection and the method which Bossi claimed was a physiological one, inasmuch as it excited uterine contractions. The recorded cases showed that it was possible to dilate the cervix when it was still intact by this instrument,

but such a procedure entailed great danger of tearing the tissues of the cervix. The average length of time required in cases in which the canal was intact at the time the operation was begun was 24 minutes, while in cases in which it was partially obliterated at the commencement of the operation it was 16 minutes. These figures showed that this was the most rapid method of completely dilating the cervical canal available, short of making incisions into the tissues or practising vaginal Caesarean section. The after-histories of the recorded cases proved further that there was very little risk of sepsis. The dilatation of the cervix could, however, hardly be called physiological, since the canal was dilated as a whole and there was no obliteration of its cavity. The most serious objection which could be urged against the use of such powerful dilators was the grave risk of tearing the tissues of the cervix as the result of the forcible dilatation. That dangerous tears of the cervix might and did occur could not be denied, but long series of cases had been published both by Bossi and Leopold in which no tears or only slight tears had resulted. Severe tears of the cervix were met with in only 4 per cent. of Leopold's 47 cases and in somewhat less than 3 per cent. of Bossi's last 107 cases. No case had so far been recorded in which the death of the patient could be attributed to the use of the dilator. Dr. Blacker gave the results of ten cases in which the instrument had been used by his colleague, Dr. Herbert R. Spencer, or himself. The conclusions which he (Dr. Blacker) came to were that in Bossi's dilator they had a means of dilating rapidly the cervix which was applicable both to cases in which the cervical canal was still intact and to cases in which it was partially dilated. In the former class of cases, however, there was a very great danger of tearing the tissues. This danger existed even in cases where the cervix was already beginning to dilate and depended rather on the degree of softening present than on the amount of dilatation. However, even in the most favourable conditions lacerations might occur and therefore the dilator should only be used in the most urgent indications—that is to say, in cases where grave danger existed to the life of the mother or to that of the child and where rapid emptying of the uterus was likely to lessen such danger. Happily such cases were of very rare occurrence. Bossi's method should not be used for placenta prævia or in the induction of premature labour. Faulty methods were no doubt responsible for some of the unfavourable results but the instrument afforded a good means of rapid and complete dilatation where the cervix was obliterated and the rapid emptying of the uterus was indicated.

LIVERPOOL MEDICAL INSTITUTION.

The Acid Extract of the Duodenal Mucous Membrane as a Remedy in Diabetes Mellitus.—The Hematology of Pregnancy and the Puerperal State.—The Complications of Pneumonia and their Treatment.

A MEETING of this society was held on Jan. 18th, Mr. FRANK T. PAUL, the President, being in the chair.

Dr. J. HILL ABRAM read a note on the Acid Extract of the Duodenal Mucous Membrane as a Remedy in Diabetes Mellitus, which will be found on p. 220 of our present issue.—Professor W. CARTER considered Dr. Abram's communication as most hopeful and full of encouraging possibilities in the treatment of a disease which, when occurring in patients as young as one of his, had always been regarded as fatal. He for one thanked him heartily for having unreservedly placed in their hands his methods.—Professor MOORE, Dr. R. J. M. BUCHANAN, Dr. A. STOKES, Dr. E. T. DAVIES, Dr. J. GRAHAM MARTIN, and Dr. O. T. WILLIAMS also spoke.

Dr. J. O. M. GIVEN read a paper on the Composition of the Blood in Pregnancy and the Puerperal State. It was based on the investigation of 12 cases of labour in which the blood was examined before and after labour and at stated intervals during the lying-in period. A marked leucocytosis of the polymorphonuclear type occurred immediately after labour and rapidly sank to normal by the end of the first week. A progressive increase in the number of the lymphocytes then occurred, until at the end of the second or third week they were more numerous than the polymorphonuclear cells. The influence of premature labour, stillbirth, albuminuria, &c., on the blood count was noted.—The PRESIDENT expressed his regret that time would not permit of any discussion on Dr. Given's valuable and interesting paper.

Dr. NATHAN RAW read a paper on the Complications of Pneumonia which he had met with in an observation of 1832 cases. He referred more especially to empyema, pericarditis, endocarditis, and the acute general infections produced by the pneumococcus, such as septicæmia, meningitis, arthritis, and peritonitis. Dr. Raw briefly referred to the treatment in each condition.—Professor CARTER referred to two conditions in pneumonia not alluded to by Dr. Raw—one at the onset of the disease where the engorgement was sometimes so general as to threaten life. The patient sat up, the right heart was over distended, the pulse was small, the face was pale or livid, and the respiration was laboured. In this condition bleeding was followed by speedy relief. The other was the violent delirium which sometimes followed the crisis; opium, which would possibly have killed the patient at an earlier stage, would now save his life. Thirdly, Professor Carter thought that, considering the intense coagulability of the exudate and the fact that it contained a large amount of calcium salts, preparations of this metal should not be administered at any stage of the disease.—Dr. ABRAM said that in a healthy subject complications were less often seen than in almost any other infective disease. They were mainly due to previous damage—e.g., pneumococcal endocarditis implanted upon old valvular trouble. Many complications, too, were due to secondary infections, as in a congenital heart case under his own care where the infective trouble was proved to be streptococcal in nature. Dr. Abram had observed that the onset of pericarditis was often marked by orthopnoea. He was opposed to the use of the needle without preliminary exposure of the pericardial sac. The great difficulties of diagnosis had been pointed out by Trousseau. Dr. Abram could not agree that jaundice was often seen in right-sided cases; in the early stages jaundice was the result of toxæmia and not serious, and in the later stages it was often the expression of an infective cholangitis and most deadly. He corroborated Professor Carter's remark respecting delirium following the crisis and recommended the use of opium combined with digitalis.—Dr. W. B. WARRINGTON remarked that among the complications seen by him were apical abscess of the lungs, the diagnosis being made by the persistent presence of elastic fibres in the sputum with diplococci and no tubercle bacilli; extensive and confluent hæmorrhages under the skin, the necropsy revealing pneumonia only; gangrene of the lungs; and apparently primary pneumococcal meningitis. Dr. Warrington insisted on the importance of suspecting pro-pericarditis in cases of empyema in children which did not pursue a normal course and alluded to the valuable papers of Dr. J. A. Coats.—Dr. A. G. GULLAN related two cases of pneumonia in which typical relapses occurred after 24 hours of normal temperature. These relapses both lasted about eight days, terminated by crisis, and were accompanied by the physical signs of lobar pneumonia in another part of the lungs. Dr. Gullan also referred to the chronic pneumonia or permanent consolidation of the lobe affected which occasionally followed acute lobar pneumonia, an example of which he had seen in a woman, aged 54 years.—The following members also took part in the discussion: Dr. BUCHANAN, Dr. E. E. GLYNN, Mr. W. STOCKDALE, Dr. E. T. DAVIES, and Dr. J. LLOYD ROBERTS.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Sleeping Sickness in Uganda.—Use of Storaine as a Spinal and Local Anæsthetic.—Relation of Spirochaete Pallida to Syphilis.—Exhibition of Spirochaetes.

A MEETING of this society was held on Jan. 17th, Dr. J. O. AFFLECK, the President, being in the chair. Captain E. D. W. GREIG, I.M.S., read a communication illustrated by numerous lantern slides on Sleeping Sickness in Uganda. He said that since the epidemic broke out fully 100,000 natives had died in Uganda since 1900. The work of investigation was commenced in May, 1903. The disease ran an extremely chronic course, three to four years being usual. The lymphatic glands underwent enlargement and formerly it was a usual practice of the slave dealers to examine the posterior cervical glands of the slaves and to reject any in whom these glands were enlarged. The patient's temperature remained normal for long but when the nervous symptoms developed the temperature during the last six to seven months of the patient's life underwent a daily rise. During

the week immediately preceding death, however, the temperature gradually fell until it became that of the surrounding air. The juice from the enlarged glands showed the presence of the characteristic parasite so that the disease could be diagnosed at a very early stage. This was of great importance as regards the migration of the individual and the risk of spreading the disease to districts which formerly were free from the disease. The axillary and later the inguinal glands underwent enlargement. The nervous symptoms manifested themselves in a peculiar facies, marked tremor of the tongue, ataxic gait, and slowness of speech; tremors of the muscles of the hands were also present. There might be acute mania or nervous exaltation. The patient gradually became more and more emaciated until he was merely skin and bone, completely bedridden, and with numerous bedsores and jigger sores. It was only during the last week of life to which the term "sleeping sickness" might truly be applied. The parasite was not present in the cerebro-spinal fluid at an early period of the disease but during the nervous symptoms it might be obtained from the cerebro-spinal fluid. The presence of the trypanosome was synchronous with the nervous symptoms. As regards the blood, anemia was not marked, there was no great reduction in the number of the red blood corpuscles, and, indeed, their number might even rise above the normal as to 6,000,000. The hæmoglobin might also rise above the normal amount. The mononuclear leucocytes were also increased in number. In the brain the convolutions were flattened and there was an increase in the subarachnoid fluid. Microscopically there was a characteristic perivascular infiltration of lymphocytes and plasma cells (small and large lymphocytes, plasma cells, and granule cells). As a terminal invasion the diplostreptococcus might be found. In the stomach underneath the mucous membrane a number of petechial hæmorrhages might be seen. These, when digested by the gastric juice, gave the appearance of charred patches. The parasite received the name of the trypanosoma Gambiense. In the blood or cerebro-spinal fluid it was actively motile and was about three times as long as a red blood corpuscle. The body of the parasite possessed a large nucleus and a small centrosome. It possessed a large food vacuole and along its dorsal surface a fine fringe ran. At the ends were one or two free flagella. From 50 to 70 per cent. of apparently healthy natives harboured this parasite in their blood. Many of these died after a longer or shorter period, while others had apparently escaped. In the non-sleeping sickness area the parasite had never been found. Experimental work had been done on monkeys, cattle, sheep, dogs, guinea-pigs, &c. Cerebro-spinal fluid was injected into these and for months they might remain without evidence of the disease. In all the monkeys a form of malarial parasite was found in the blood but before inoculation trypanosomes were absent from their blood. The disease remained very closely confined to the margins of the Lake Nyanza and its islands and to the margins of Albert Nyanza. The tsetse-fly (*Glossina palpalis*) was the carrier of the parasite. This fly laid no eggs but a single actively motile larva which three weeks later was hatched out (pupifera). In the stomach of this fly an enormous multiplication of trypanosomes took place. They were seen to be undergoing division into several types, probably sexual forms. This multiplication took place in 10 per cent. of the flies. A longitudinal fission of the parasite was the rule. The distribution of the fly corresponded very exactly with the distribution of sleeping sickness. The tsetse fly was very widely distributed over Africa but it required a shady undergrowth for its development. In the experiments the flies were allowed to feed on the blood of infected men and then on monkeys. The interval between these acts varied from eight to 48 hours, and in all cases the disease was transmitted to the monkeys. On investigation it was found that the flies in the affected belt contained trypanosomes. As regards treatment, arsenic in the form of Fowler's solution given subcutaneously was tried. During its administration the parasites were absent from the blood but they reappeared and multiplied when arsenic was discontinued. It was the wild game which seemed not to suffer from the disease but which harboured the parasite, and so tame domestic animals became infected. Where these wild animals existed no tame animals could exist. These wild animals, as also some of the natives, appeared to be immune to the disease. Captain Grig received a cordial vote of thanks for his interesting communication.

Mr. G. L. CHIENE read a communication on the Use of Stovaine as a Spinal and Local Anæsthetic. He said that the use of a general anæsthetic was always a source of possible danger to the patient and now when the dangers due to the actual operative procedure had been reduced to a minimum the anæsthetic might be regarded as the most dangerous factor in many operations. Bier first attempted the production of anæsthesia by spinal injection. Cocaine was used but as the after results were often of a most unpleasant or even dangerous nature the method for a time fell into disuse. In February, 1904, Fournier, a French chemist, first brought before the profession the hydrochlorate of amyleine which he named stovaine. This product when injected into man slowed the pulse and caused contraction of the pupil. Pallor was not induced but often flushing supervened. Dyspnoea, oppression, uneasiness, or excitement was absent and there was no tendency to syncope. It was certainly much less toxic than cocaine and so could be given in larger doses if required. As after-result there was usually a slight rise of temperature which might last for some days. There was little tendency to sickness or vomiting, while headache and spinal neuralgia were rarely present. The general condition was good and the patient could enjoy an ordinary meal. Reclus in July, 1904, gave the results of nine months' experience with stovaine as a local anæsthetic. He employed it in doses twice the strength of cocaine. Chaput maintained that many laparotomies could be performed under spinal anæsthesia with stovaine. In 100 cases 45 operations were performed on the legs, 26 on the perineum, and 29 on the abdomen (hernias, hysterectomies, appendectomies, and ovariectomies). He stated that it was very useful in fractures and dislocations of the lower extremities. The height to which the anæsthesia rose varied greatly with the dose and his failures occurred only when small doses had been given. In his experience the after-results of stovaine were much less severe than those of cocaine. The dose injected varied from four to eight centigrammes and he did not care to employ it in patients over 65 years of age. Mr. Chiene had employed this drug on various occasions since October, 1904, combined with hemisine. In his experience a larger dose was required to produce spinal anæsthesia than that recommended by foreign authorities. He used Tuffier's solution, 10 per cent. of stovaine in sodium chloride solution. Sterilised solutions of the drug were supplied in ampoules. After injection into the spinal canal a sensation of pins and needles was felt in the legs and in about seven minutes the patient was unable to lift the limbs. At this time sensation to pain was lost though that to touch remained. Anæsthesia commenced in the perineal region, then affected the toes and feet, and passed gradually up the limb. It passed off in the reverse order. The operations which he had performed under spinal anæsthesia induced by stovaine included inguinal hernias, transplantation of tendons, removal of tuberculous glands in the groin, operation for severe traumatic flat-foot, hæmorrhoids, varicose veins of both legs, &c. Mr. Chiene was quite satisfied that with more experience both in technique and in the dosage of the drug failures would be exceptional. Lumbar puncture was now a routine method for diagnostic purposes in medicine and accidents were rarely heard of. It was too soon to compare the risks with those of general anæsthetics but it must be allowed that this method might be preferable in many cases. It was stated by some authors that gangrene of the skin occurred at the point of injection, but in Mr. Chiene's experience with the combination of drugs already mentioned he had not had a single case of gangrene of the cutaneous tissues.—The communication was discussed by Dr. T. D. LUKE, Mr. F. M. CATRO, and Mr. J. W. STRUTHERS.

Dr. THEODORE SHENNAN read a paper on the Relation of Spirochæta (Spirochaeta) Pallida to Syphilis.

The following specimens were exhibited:—

Dr. JAMES CAMERON: Strangulated Testicle from a case of Strangulated Hernia in an infant aged six weeks. Operation was followed by recovery.

Dr. H. DOUGLAS WILSON (Harrogate): Radiograms of the Hands from a case of Tophaceous Gout.

EPIDEMIOLOGICAL SOCIETY.—A meeting of this society was held on Jan. 19th. Dr. J. F. W. Tatham, the President, being in the chair.—Mr. W. Hunting, F.R.C.V.S., read a paper on Glaners in Horse and

Man. Though the disease had been scheduled since 1869 there were no very trustworthy statistics before 1881, since which date 44,943 horses had been returned as dying from glanders, giving an average of 2000, of the probable value of £40,000 or £50,000, per annum. Yet it would not be difficult to stamp it out, for 70 per cent. of the cases occurred in London and 90 per cent. in the home counties, the only other centre being Glasgow, and it was not one that spread with any rapidity; but the reluctance of the Treasury to give the money for compensation had hitherto prevented the application of the provisions of the Diseases of Animals Act, the Board of Agriculture urging the plea for inaction that the loss of human life through it was insignificant, not more than two, and once only six deaths appearing in the Registrar-General's annual returns. There was, however, strong ground for believing that the true mortality was very much greater, probably nearer 100, the vast majority being erroneously reported as rheumatic fever, cellulitis, pyæmia, &c. Inoculation and ingestion were the means by which the disease was communicated, ingestion with water and fodder being by far the more frequent. The incubation period was very variable, from two weeks to two months, though the animals might appear in perfect health for a year or even longer. When complicated with pneumonia or pleurisy it might be fatal in a few days or after apparent recovery a relapse might occur. The typical clinical symptoms in the horse were enlargement of the submaxillary glands, with nasal discharge and ulceration of the mucous membranes of the trachea, larynx, and nares, swelling of the lymphatic glands and vessels with small tumours under the skin, "farcy buds," and swelling of one or more of the legs. The only constant lesions found post mortem were nodules in the lungs but the swelling of the bronchial glands always observed in tuberculosis was rare. In 1000 post-mortem examinations made by the veterinary inspectors of the London County Council 482 showed lesions in the lungs only, the nasal mucous membrane was ulcerated in 378, that of the larynx in 179, and of the trachea in 201, the lungs being also implicated in every case. So long as unbroken nodules in the lungs alone were present the disease did not appear to be communicated to other and healthy animals, but such horses might at any moment develop ulceration or the glands might burst and the animal become highly infective. The discovery of mallein in 1890 by a Russian veterinary surgeon furnished an almost infallible means of diagnosing the existence of the disease in the latent stages; like tuberculin, mallein was an extract of the bacilli of the disease, the injection of which into a healthy animal gave rise to no symptoms, but when glanders was present there was not only a characteristic febrile disturbance but a swelling at the site of the injection, this double reaction making the test more decisive than that of tuberculin, but the intensity of the reaction bore no relation to the extent or the duration of the disease, simply disclosing its presence. The existing regulations were wholly inadequate, the enjoined notification, diagnosis by a veterinary inspector, slaughter and compensation to one-fourth of the value of the animal, but there was no provision for the isolation of "contacts" and the disease might go on spreading until the owner sold off his stock to form foci elsewhere in perhaps a score of stables in place of the one originally invaded. Without mallein diagnosis was impossible in the early stages and in the later, when it was obvious, the owner might, in consideration of the meagre compensation, prefer to conceal the fact and get the utmost possible work out of the horse until it was about to die and no longer of use. Some cab-owners habitually and knowingly bought glandered horses, deferring notification so long as possible or selling their whole stock if threatened by a raid from the police or inspectors. As to the prevalence of glanders in man, the Registrar-General's returns gave no notion of the real number of cases; they were never reported by private practitioners and those correctly diagnosed in hospitals had always been admitted under false descriptions—rheumatic fever, typhoid fever, pneumonia, septicæmia and pyæmia, cellulitis, even confluent small-pox, influenza, and "blood poisoning"; in fact, the clinical symptoms in man were far less definite than those in the horse, and it was rarely that a diagnosis could be made with certainty save after a bacteriological examination of the fluid from the cutaneous nodules or of the subcutaneous infiltration of the "cellulitis." Mr. Hunting then gave notes of 11 such cases

admitted under various names into hospitals and a description of the necropsy of one by Dr. Charles Creighton. The mode of infection in man was commonly supposed to be inoculation, but this he believed to be far less frequent than ingestion through "eating with unwashed hands" after handling infected horses. Local manifestations which would indicate the point of inoculation were very rare. Nodules in the lungs were found post mortem, but an absolute diagnosis was even then seldom possible except bacteriologically, though glanders should be suspected in all cases of "cellulitis" or those simulating rheumatic fever, erysipelas, &c., in horse-keepers, cabmen, and others employed in stable-yards.—A letter was read from Dr. E. W. Goodall in reference to the two cases admitted to the Eastern Hospital as typhoid fever. In the first case the presence of intra-muscular abscesses, pathognomonic of glanders but never occurring in typhoid fever, led him to an immediate diagnosis, but he should not have suspected the nature of the second case if it had not been for the man's occupation.—Sir John McFadyen, while agreeing in every essential matter with Mr. Hunting, considered his statements as to the non-infectivity of the early stage as rather too strong, for since the extension to the trachea was due to the escape of bacilli from the pulmonary nodules they might easily at this stage be carried a little farther and render the saliva and nasal mucus infective or escape in coughing.—Dr. H. Armstrong deprecated compensation as tending to encourage the trade in glandered horses and to defeat its ostensible purpose.—Dr. W. Bulloch had seen seven cases at the London Hospital. In the 15 years before the opening of the bacteriological laboratory in 1900 they had no record of a single case, but so soon as bacteriological examinations were systematically carried out they had six cases in two years. Few medical men had ever seen a case, so that it was not surprising that they should fail to recognise one when they met it, though the occupation of the majority of the patients ought to suggest the nature of the disease. One case sent in by the medical officer of health of Shoreditch had been diagnosed by successive practitioners as acute rheumatism, pneumonia, acute rheumatism again, and, lastly, confluent small-pox when the cutaneous nodules began to break up, though they contained not pus but a yellow glairy fluid. Mallein could not be recommended with the human being as, apart from possible danger, it failed to give the local swelling which constituted its chief diagnostic value in the horse.—Mr. F. T. G. Hobday, F.R.C.V.S., remarked on the small number of cases among men employed in cab-yards which were hotbeds of the disease. In one yard 90 horses had been slaughtered in 18 months and in another 15 out of 16 reacted. Inspectors had no power to touch animals that did not show clinical signs; they ought to have power to use the mallein test on all "contacts" and to isolate if they did not slaughter them. Frequently when a horse had been condemned the owner sold off the rest, many, no doubt, already diseased; others regularly kept glandered horses for night work until they broke down. He considered the fee of £2 for notification was too liberal and the quarter value in compensation was insufficient, tending to encourage the delay of notifying till the animal had no more value.—Dr. M. Richards had seen five cases of glanders in man, three of them quite recently in Croydon. In two of these the source of infection could not be traced.—Dr. J. McIntosh McCall mentioned the case of a stable in Glasgow where among over 100 horses only four did not react and two-thirds had no clinical symptoms, appearing in perfect health.—Dr. E. F. Willoughby referred to a case recently quoted in *Public Health* of a veterinary surgeon at Bucharest who contracted glanders through wounding his hand in a post-mortem examination. The initial local lesion was well marked and he died with intense pneumonic and pyæmic symptoms and abscesses in the muscles and all the viscera, cutaneous abscesses, and bullæ.—Mr. Hunting, in reply, mentioned a case of special interest which, taken up by Dr. T. Orme Dudfield in the press, led to the issue of the existing regulations. A girl with a young child in her arms was sitting at the door while their father was giving some medicine to a horse. The animal coughed and bespattered them with mucus and both the girls died shortly afterwards from glanders. Yet he had known of but two horse knackers in London contracting the disease though he had seen more than one cut his hands badly. But the discoverer of mallein and at least half a dozen engaged in its preparation had succumbed to the disease. The descriptions given

in text-books of glanders in man were in very few instances realised in actual practice, intra-muscular abscesses being the only constant and pathognomonic symptom.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Jan. 12th, Mr. E. Ward being in the chair. The following cases, pathological specimens, &c., were shown. Professor A. S. F. Grünbaum: (1) An Intestinal Worm *in situ* (microscope); and (2) *Spirochæta Pallida* (syphilis).—Mr. W. Thompson: (1) Fibroid which prevented reduction of strangulated umbilical hernia; and (2) large Fibroid (35 pounds).—Mr. E. Solly: A large Adrenal Tumour removed by anterior incision (microscopic section).—Dr. F. S. Mackenzie: (1) Strangulated Obturator Hernia; and (2) a specimen of a Cloacal Opening in a child. —Mr. Michael A. Teale: A case of (1) Primary Melanotic Sarcoma of Caruncle of the Left Eye (slide).—Mr. H. Littlewood: (1) Extensive Growth from the Skin of the Face (patient); (2) Perforated Gastric Ulcer treated by excision and without drainage (patient and specimen); and (3) some Ovarian and Uterine Tumours. —Dr. A. G. Barrs: Pseudo Tabes and Facial Palsy following gonorrhœa. —Dr. E. F. Truvelyan: (1) A case of Wasting of the Leg of four years' duration; and (2) a case of Aphasia eight months after the onset of right hemiplegia. —Dr. A. L. Whitehead: Specimens from a series of cases of Sub-mucous Resection of the Nasal Septum. —Dr. J. B. Heller: (1) Uterus with Myoma removed by vaginal hysterectomy; and (2) Uterus with Placenta *in situ* from a patient who died from hæmorrhage before labour. —Dr. W. H. M. Telling: (1) A specimen of Tricuspid Stenosis; (2) Chronic Nephritis with Extreme Atrophy of the Abdominal Vessels in a woman, aged 25 years; and (3) with Mr. Littlewood: Viscera from a case of Melanotic Sarcoma. —Dr. T. W. Griffith: (1) A case of Charcot's Disease of the Knee-joint; (2) a case of combined Palsy of the Hypoglossal and Sixth Nerves; and (3) a specimen of Oblique Fracture from a rickety subject (dissecting room). —Mr. G. Constable Hayes: A case of Syphilitic Ulceration of the Nose simulating lupus. —Dr. Griffith read a paper based on a series of specimens illustrative of Abnormalities of the Alimentary Canal. In connexion with the closure of the vitelline duct, a passing reference was made to the comparatively common diverticulum of Meckel with its various sources of danger and the much rarer narrowing or complete interruption of the gut which might take place at this situation was discussed, with special reference to the views of Sutton and Shattock. The aberrant conditions arising in connexion with those normal diverticula, which lead to the formation of the liver and of the respiratory tract, were then discussed under the headings of abnormal diverticula and of stenoses and obliterations. An analogy was drawn between the diverticulum of the duodenum, which was sometimes found just above the crifice of the common bile-duct, and the dimple of peritoneum, sometimes forming a tube of considerable length, which may be found alongside of the obturator artery at the upper part of the thyroid foramen, or the similar depression which so often exists alongside of the external iliac vessels as they pass under Ponsart's ligament, and which may become enlarged to form the sac of a femoral hernia. The former was due to the normal outgrowth which results in the formation of the ampulla of Vater and of the bile and pancreatic ducts, carrying alongside of it a pouch of duodenum, while the latter were caused by the parietal peritoneum being drawn down by the lengthening obturator and femoral vessels respectively. The diverticula of the œsophagus, due to corresponding causes, were described as being situated not close to the permanent opening into the respiratory tract—not close, that is to say, to the superior aperture of the larynx, but much farther down, and the connexion of this with the manner of development of the trachea was pointed out, as was also the difficulty of discriminating between these true diverticula and those commoner ones which were caused by the traction of tuberculous glands. Of complete interruption of the gut in the neighbourhood of the orifice of the common bile duct a good specimen was shown from the body of a child who had lived only a few days. The two blind ends of the duodenum were found close together and the bile duct opened into the beginning of the distal segment. In this case there was a large meningocœle with other abnormalities of the brain; the whole of the large as well as the small intestine retained its primitive peritoneal relations. The condition was suspected

before the body was opened at the necropsy because, though there was imperforate anus afterwards found to be due to atresia of the rectum, the persistent vomiting which was present was not associated with abdominal distension. Dissections were then shown of a series of specimens of imperforate anus and of atresia of the rectum and the explanation of the various examples was given from the developmental point of view, reference being made to the work of Dr. F. Wood Jones. —Mr. J. F. Dobson read a paper on Retro-pharyngeal Abscess. —Mr. J. Stewart made a communication on Enucleation of a Fibro-myoma of the Uterus during the fifth month of Pregnancy; pregnancy was uninterrupted.

NEWCASTLE-UPON-TYNE CLINICAL SOCIETY.—A pathological meeting of this society was held on Jan. 11th, Mr. H. B. Angus being in the chair. —Mr. Angus showed: 1. A Seven Months Extra-uterine Foetation which he had successfully removed from a woman, aged 38 years, who had not been pregnant before. After a period of amenorrhœa she had several attacks of abdominal pain with vaginal hæmorrhage. The foetation lay in the left side of the pelvis but whether between the layers of the broad ligament or between the latter and the meso sigmoid could not be accurately made out. (The specimen was referred to a pathological subcommittee for further investigation.) 2. An Incomplete Tubal Abortion. 3. An Intra-peritoneal Rupture of the Gravid Tube. 4. Two specimens of Enlarged Prostate, both removed by the *suprapubic route*. The first patient was a man, aged 70 years. A mulberry calculus was found in the prostatic pouch. Though there was little bleeding at the operation reactionary hæmorrhage was so severe as to necessitate gauze packing. The man made a good recovery. In the second case, though the prostate was large, inviting enucleation, this was found difficult and it could only be removed in pieces. 5. A series of Vesical Calculi, the most interesting being a group of seven uric acid stones removed together with a small adenoma from the median lobe of the prostate. —Mr. John Clay showed: 1. An Epithelioma of the Pharynx from a female patient, aged 28 years, who had suffered from dysphagia for 14 years. 2. The Uterine Appendages from a patient who had acute diffuse tuberculous peritonitis. The symptoms were so sudden and severe that the peritonitis was thought to be due to the perforation of a hollow viscus. 3. A Granuloma of the Nail Bed from a patient the subject of diabetes. —Mr. G. Grey Turner exhibited: 1. Two specimens of Ectopic Gestation. The first was from a patient, aged 24 years, the mother of one child 13 months old. She was suckling and only missed one period. In the first attack of abdominal pain there was no uterine hæmorrhage but at the operation a four months foetus was removed from the right broad ligament. In the second case the patient menstruated in November and in December she was seized with a severe abdominal illness; there was no uterine hæmorrhage. The peritoneal cavity was full of blood which came from a very small tear in the uterine end of the tube; the ovary contained a recent corpus luteum. 2. A Patient Meckel's Diverticulum excised from a baby five weeks old. The patient was nursed at home by the mother and recovered without a bad symptom. 3. A Papilloma removed from the bladder of a man, aged 44 years, whose only symptom was slight hæmaturia. The diagnosis was made with the cystoscope. 4. The parts removed by epididymectomy from a patient who had Double Tuberculous Testicles. 5. A Fibro-adenoma from the Breast. It had been present as a small lump for years and only began to enlarge during pregnancy. 6. Calculi removed simultaneously from either duct of Wharton. —Mr. W. G. Richardson showed: 1. A Kidney with a large Calculus in the Pelvis removed post mortem; the opposite organ was large and normal. Mr. Richardson pointed out that with a painless lesion one kidney might be destroyed without giving rise to symptoms so long as the other kidney was healthy. If a patient had one functional kidney only and that became diseased symptoms at once became prominent; hence the frequency with which a single working kidney was met with in renal surgery. 2. Two examples of Prostatic Calculi removed by suprapubic cystotomy. Both were felt per rectum and by the sound and after being pushed on into the bladder were seen there by the cystoscope. In the first case the bladder was healthy and was entered, immediately healing per priam; in the second case drainage was employed. 3. A Large Number of Small Calculi removed by Lithotripsy Evacuator. 4. An Enormous Pedunculated Papilloma removed from the

Bladder. The patient had only once previously suffered from hæmaturia but operation became urgent because a process of the growth completely blocked the urethra, causing retention.—Mr. George Foggin showed a series of ophthalmic specimens: 1. An Epithelioma of the Cornea from a man, aged 62 years, who had been two years under treatment for supposed corneal ulcer. The orbit was eviscerated but recurrence took place and death ensued nine months after operation. 2. Sarcoma of the Iris from a girl, aged 15 years. Now, five years after removal of the eye, there was no recurrence. 3. Glio-sarcoma of the Retina. The patient was first seen at the age of six months but the parents refused operation; when three years old there was extreme proptosis. The orbit was eviscerated but rapid recurrence took place with sudden death four months after operation. 4. Hydatid Cyst of the Orbit removed from a child, two and a half years old. 5. An Eyeball with a Piece of Sheet Copper imbedded in it for 19 years. There was a thick bony cup surrounding the foreign body.

ROYAL ACADEMY OF MEDICINE IN IRELAND:
SECTION OF PATHOLOGY.—A meeting of this section was held on Jan. 5th, Dr. J. F. O'Carroll, the President, being in the chair.—Professor E. H. Bennett showed two specimens of Fracture of the Astragalus and said that some 25 years ago he published a paper on the supposed fracture of the tubercle of the astragalus, raising the question whether it was a fracture or not or a vestige of the os trigonum tarsi. The first of the two specimens exhibited on the present occasion showed a united fracture of the same region of the bone, without doubt a fracture well and truly knit. The anterior part of the tubercle with the groove for the tendon of the long flexor of the great toe had been broken and united with the minimum degree of deformity. There was, however, no means of knowing how the fracture had been produced. The second specimen showed a fracture taking effect on that part of the head of the bone that rested on the calcaneoscaphoid ligament, and it had not passed to any deeper extent than the cartilage.—Dr. R. Travers Smith exhibited some of the thoracic viscera of a man, aged 70 years, who had died in the Whitworth Hospital from flat-celled cancer of the œsophagus. The growth had caused a very narrow stricture and had grown by direct extension into the outer coat of the descending aorta. Numerous small secondary deposits were also found in the outer coat of the aorta and the bronchial lymph glands were cancerous. Imbedded in the wall of the left ventricle near the auriculo-ventricular groove was a secondary deposit of the size of a large hazel-nut which on microscopical examination made by Dr. H. O. Earl showed typical flat-celled arrangement. There were no metastases of the disease below the diaphragm with the exception of a cancerous deposit in a single lymph gland situated under the peritoneum on the anterior aspect of the stomach near the œsophagus and nearer the lesser curvature than the great. Dr. Travers Smith laid stress upon the frequency with which this gland was affected in internal, especially abdominal, cancer. He also spoke of the difficulty in fully explaining how the secondary deposit in this case had reached the heart.—The President said that an interesting point had been raised—namely, the dissemination backwards against the lymph stream. This must often happen also in various forms of tubercle. The particles carried by her have gone against the stream or else had been carried by the subclavian vein, returned by the vena cava, and going through the pulmonary system was deposited by the coronary artery in the heart.—Professor Bennett said that the same thing must occur in cancer *en cuirasse*, as the cancer certainly did not follow the lymphatic stream.—The President showed a hydrocephalic brain of a boy 17 years old, who had suffered for about six years from headaches and frequent subcomatose attacks lasting a few days. The cranium was not much larger than normal and was fully ossified. The ventricular cavities were considerably dilated but not to the degree of thinning the brain substance excessively. The greatest thinning was at the lower anterior part of the lateral ventricle where the cortex was adherent to the underlying bone. During the last couple of months of the boy's life a colourless watery fluid, recognised to be cerebro-spinal fluid, used to drip freely from time to time from the left nostril. It was evident that this discharge from the nostril came from the left ventricle by way of the adhesion of the temporoparietal lobe to the body of the sphenoid. During life the boy had been subnormal in intelligence but by no means an imbecile; he had learned to read

and to write and could perform simple mental calculations. He was of average height and weight and the head was not abnormally large but the sexual organs were poorly developed. The skin, of normal texture, seemed somewhat tightly drawn over the limbs as it ordinarily is on the outside of the thigh; but there was no scleroderma. There had been no ataxy. In walking his toes caught the ground now and again and Babinski's toe-extension sign was present, while increased knee-jerk and ankle clonus were absent. There was no proof of hereditary syphilis; his birth had been instrumental.—Dr. T. G. Moorhead described a case which had been under his care and in which hydrocephalus had occurred after pyrexia, lasting for 60 days, in a man, aged 65 years. There was no obstruction to the outflow and there was increase of the subarachnoid fluid. The cerebro-spinal fluid was distinctly turbid and he cultivated the bacillus coli communis from it. He regarded the hydrocephalus as due to inflammation of the ependyma.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Jan. 17th, Mr. T. J. Dabell, the President, being in the chair.—Dr. Arthur Whitfield of King's College Hospital, London, gave an address (with lantern illustrations) entitled "The Cutaneous Manifestations of Acquired Syphilis." In introducing the subject Dr. Whitfield criticised the way in which specific eruptions were often classified according to the lesion. It was customary, perhaps, to regard syphilis as a series of causes of disease rather than as a chronic and consistent disorder, and it was much better to recognise the lesions as syphilis than to use such terms as syphilitic psoriasis. In any doubtful case of primary sore it was wiser to await the appearance of additional symptoms than to make the diagnosis of syphilis erroneously, even if it were only in 1 or 2 per cent. of the cases. It was a serious thing to put a patient under a three years' course of mercury unnecessarily, apart from the injury to his feelings and self-respect. Dealing first with the initial lesion it was shown that induration was not always marked but depended rather on the local distribution of blood-vessels. The defined, rolling edge was its most characteristic feature but it was not always possible to diagnose syphilis from this alone, for on the one hand the initial lesion might not be characteristic and on the other apparently typical sores might be followed by no other symptoms. Other early symptoms to be waited for were adenitis and, most characteristic of all, an indurated lymphangitis on the dorsum penis, often bifurcating at its root. Proceeding to the earlier rashes, the usual characteristics of these were pointed out to be their generalisation, superficial site, multiformity, and absence of grouping, but these had exceptions. Illustrations were shown of the large papular, giant papular, small papular, follicular, corymbose, scaly, and bullous varieties, and attention was drawn to the histological basis of these various lesions. Passing to the early relapsing eruptions these were shown to be grouped, extending more deeply and less generalised but still usually symmetrical. Striking examples were shown of the psoriasiform and late corymbose conditions with atrophy of the centres of the patches and their histology was illustrated. Among the later rashes were shown a papular one with tendency to overgrowth, the cutaneous or grouped gumma, the late palmar and plantar syphilide with hypertrophy, and the large non-grouped subcutaneous gumma. The effect of syphilis on the skin of seborrhœic subjects was also explained. One of the most important points in treatment was never at any stage to overdose the patient with mercury, which, if it occurred, nearly always meant that the case became more resistant to treatment ever afterwards. Follicular eruptions were as a rule obstinate cases to treat. As the disease became older the potency of local treatment increased, while that of constitutional treatment diminished. An instance was given of a late palmar syphilide which after resisting all forms of mercury and iodide yielded satisfactorily to the x rays.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY.—A meeting of this society was held on Jan. 11th, the President, Dr. H. W. Sykes, being in the chair.—Dr. W. R. Dakin read a paper entitled, "Do we Teach our Students Midwifery?" He began his paper by laying before the society some of the statistics available on the results of midwifery practice in this country, contrasting the death-rate in the lying-in hospitals with those obtained in private practice. He pointed out the striking results

obtained when antiseptic principles were first observed in lying-in hospitals, instancing the reduction in mortality by Semmelweis from 12 to 2 or 3 per cent. He further pointed out that at the General Lying-in Hospital, York-road, during the last 16 or 17 years no case of blood poisoning occurred which had started there. He then proceeded to show that the mortality from septic puerperal disease in the years 1835 to 1890 was 2.4 per 1000 births; during the period 1890 to 1895, 2.5; 1895 to 1900, 2.0; and in the single years 1901, 1902, and 1903 it was 2.2, 2.1, and 1.75 respectively. The numbers were, however, no better than in 1876 to 1880 as regards deaths from sepsis and were worse as regards total mortality. He considered that the medical men were responsible for the failure to improve. The two main causes of septicæmia were: first, that there were some medical men who did not know how to practise midwifery; and secondly, that asepsis was by a large number of medical men not considered a matter to be taken seriously in midwifery practice, although they believed that in surgery it was a vital element. The weak point was that the practice of the younger men was not devoid of septicæmia, although they had been inculcated from the very first moment in all the details of asepsis. Dr. Dakin blamed the way in which the student got his smattering of midwifery and held that the so-called practical work was simply a farce. He pointed out further the slight esteem in which the subject of midwifery was held by the examining boards, inasmuch as the student was supposed to get up the whole subject in little more than 30 lectures and could have done with it at the end of his fourth year. The student was left to obtain his practical knowledge unattended or having the services only of a qualified senior student to assist him. It might be said that independent charge of cases in this way was likely to engender habits of self-reliance, but if self-reliance was acquired on a basis of ignorance the result could only be disaster. The student should be thoroughly taught to know natural and unnatural conditions when he saw them and to conduct normal or any other labour aseptically. Dr. Dakin contrasted the much better methods prevalent in Germany, where the student was required to attend two and a half years' course regularly in a lying-in hospital and personally to have delivered four women in the presence of the teacher or the assistant physician. He urged the establishment of a large lying-in hospital. The rule would then be that a student before admission to the qualifying examination in midwifery in his fifth year, and, in fact, at the same stage as that at which he took his medicine and surgery examinations, should have attended regularly the practice of the lying-in hospital (to be established) for at least eight months and have personally delivered and subsequently attended 30 cases of labour in the following way: five cases must have been attended in the hospital under the teacher; during the time in which the labours of these five occurred he would reside in the hospital; he would have to make all the necessary examinations, abdominal and vaginal, and perform all the manipulations of delivery under the supervision of the teacher there. He would make full notes in each case, in a manner satisfactory to the teacher, of the patient's previous history, of the pregnancy, labour, and lying-in period, and of the progress of the child. The remainder of the 30 cases might be attended outside the hospital, preferably in the outdoor maternity of his own hospital. He would be still under the control of a teacher and would keep full notes of each case as before. Further, this practical midwifery work should be taken in his fifth year and not less than two years after passing his second examination. He would then appreciate something of what he was learning and he would go up for his medicine, surgery, and midwifery, which three subjects he would certainly have to practise simultaneously, at the end of his fifth year. Dr. Dakin then gave a sketch of the details of such a lying-in hospital.—The paper was discussed by Dr. G. F. Blacker, Dr. R. Hamilton Bell, and Dr. W. A. Malcolm.—A vote of thanks to Dr. Dakin closed the proceedings.

CHELSEA CLINICAL SOCIETY.—A meeting of this society was held on Jan. 16th, Dr. J. Barry Ball, the President, being in the chair.—Dr. T. Vincent Dickinson read a paper on Periodic Vomiting with Acetonæmia in Children. He said that this disease presented the following clinical picture. In the midst of perfect health without apparent or appreciable cause or error in diet or derangement of intestinal action the child, who was usually of a nervous or

arthritic diathesis, was suddenly seized with vomiting. This vomiting was produced by regurgitation without premonitory nausea as in tuberculous meningitis. The vomited matter, usually watery, was at first abundant and then diminished until the stomach was empty. Attacks occurred several times a day either spontaneously or excited by movement. The usual duration was from two to four or five days, and once at an end health was re-established immediately. During the attack there were much prostration, a clear tongue, constipation, and retracted abdomen; the pulse and temperature were slightly raised; the breath smelt of acetone, which was always found in the urine at some period of the attack. The cause had been variously attributed to the arthritic diathesis, hyperacidity of the gastric juice, faulty metabolism producing diacetic and oxybutyric acids, or xanthin and paraxanthin, or as a manifestation allied to migraine. Two theories lately brought forward were (1) that of Richiardi, insufficient function of the liver which in some cases is enlarged; and (2) that of Broca, latent appendicitis. The latest statistics by Comby of 24 cases show that in two only was the appendix implicated; 24 were girls and ten were boys, the average age being from two to ten years. There was enlarged liver in two cases; jaundice was rare; there was constipation in 30 cases; six were afebrile. These cases were met with in children of a neuro-arthritic diathesis and among the richer classes. Prognosis was almost always favourable. The treatment, founded on the idea of its being an acid intoxication, consisted in giving bicarbonate of soda in large doses, 15 grains every two hours. Edsall and Pierson claimed to have cut short the attacks by this, while Shaw and Tribe state that the vomiting itself seemed to have been more marked while taking it, although their case recovered. Griffith gave phosphate of soda without marked success, and Morgan states that morphine injections allay the vomiting and gives alkalies in some form combined with bromide of sodium. Rectal feeding and massage have their uses, and between the attacks the diet and bowels should be regulated and the general condition improved by hydrotherapy, exercises, and fresh air.

ESCULAPIAN SOCIETY.—A meeting of this society was held on Jan. 19th, Mr. W. Campbell McDonnell, the President, being in the chair.—Dr. David Ross showed a case of Chronic Hydrocephalus following Cerebro-spinal Meningitis. A male child, aged three months, was vaccinated by him and a week later had convulsions which lasted about two weeks. He lapsed into a state of stupor and was apparently blind. Kernig's sign was present. On the face, the upper arms, and the chest there appeared bluish-red spots, likened to flea-bites by the friends. The bowels were constipated, wasting was rapid and great, and he screamed almost incessantly. The retraction of the head was so great that the friends thought the neck would break. For nine months the wasting continued until the child was almost a skeleton, then he gradually began to recover, and is now a fine plump child of two years. He sees and hears well and talks a little. The head is very large and heavy but the fontanelles are closed. He moves his legs freely but has no idea of walking or standing alone. Heubner described a chronic form of cerebro-spinal meningitis which might be protracted for from two to five or even six months, and might cause the most intense marasmus. It was not impossible that these protracted cases depended upon chronic hydrocephalus or abscesses of the brain. Lenhartz of Hamburg had observed 45 cases in ten years and was convinced that the best treatment was early and protracted lumbar puncture. For retraction of the head Dr. A. Merison said he had introduced an "occipital hammer" to slip up the child's head and he found that this made a child more comfortable and kept him quieter.—Dr. L. Darro showed a healthy Appendix ten and a quarter inches in length which he had removed from a man, aged 49 years, who had died from chronic alcoholism.—The President showed an eight months' Male Fœtus with the following congenital defects: hare-lip, lumbar spina bifida, club hands with absence of the left thumb, club feet, large hernia into the cord, and cyst of the cord. He also showed a photograph and two skiagrams.

PATHOLOGICAL SOCIETY OF MANCHESTER.—A meeting of this society was held on Jan. 17th, Professor J. Lorrain Smith being in the chair.—Dr. Calvert Lockyer of London gave a lantern demonstration on the Development and Retrogression of the Corpus Luteum. The lecturer

pointed out that the majority of pathological processes associated with lutein tissue were not the outcome of changes in the corpus luteum itself but arose during the developmental stages of the Graafian follicle—i.e., before that body attained anything like its full maturity. In this way the different types of lutein cysts, also lutein hæmatomata, and even lutein abscess and calcification have, as a rule, nothing to do with the yellow body. Such changes take their origin for the most part in atresic follicles which have acquired a lutein lamina before undergoing retrogression. Mention was especially made of the type of lutein cysts which the lecturer described as "composite lutein cystomata"—large tumours, that is, which he had only found in association with vesicular mole and chorio-epithelioma. The actual causation of this peculiar type of lutein excess was still obscure but its relationship to the ovular changes could scarcely be accidental, nor did the speaker think they were secondary as did the German authority Gottschalk. The fascinating theory that lutein excess accounted for trophoblastic overgrowth had occupied Dr. Lockyer's close attention, but control investigations on ovaries from cases of normal gestation and chorio-epithelioma failed to convince him that excess of lutein tissue was peculiar to vesicular disease and chorio-epithelioma. Another difficulty which stood in the way was the possible confusion of displaced lutein tissue and decidual reaction in the ovarian stroma, and the lecturer threw out the suggestion that the lutein cell and the decidual cell were histogenetically one.—Professor R. Favell (Sheffield) showed a Uterus and Ovaries, the former containing a hydatid mole and the latter lutein cysts.—Dr. O. Oldfield (Leeds) showed a specimen with Double Lutein Cysts and Chorio-epithelioma of the Uterus.—Other preparations were shown as card specimens.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—The annual meeting of this society was held at Manchester on Jan. 19th, when the following office-bearers were elected. President: Mr. R. Favell. Vice-Presidents: Sir William J. Sinclair, Dr. D. Lloyd Roberts, Mr. Owen Bowen, Dr. Arthur J. Wallace, Dr. J. Braithwaite, Dr. C. J. Wright, Dr. John W. Martin, and Mr. Percival E. Barber. Honorary treasurer: Dr. E. Octavius Croft. Honorary general secretary: Dr. W. E. Fothergill.—A valedictory address on the Evolution of Operative Gynæcology was then delivered by Dr. Lloyd Roberts, the retiring President, which is published at p. 207 of this issue of THE LANCET.—Dr. J. B. Hellier showed a Pelvis deformed as the result of Infantile Paralysis. There was deficient development of the os innominatum of the paralysed side and the normal flattening which takes place between birth and maturity was exaggerated on the sound side, on which extra weight had been thrown. There was a difference of half an inch between the oblique diameters at the brim. The outlet was much contracted, the ischial spines being three and a quarter inches apart, while the tip of the coccyx was within one and three-quarter inches of the symphysis and deviated three-quarters of an inch to the right.—The usual dinner was held at the Queen's Hotel, Mr. Favell being in the chair.

Reviews and Notices of Books.

Die Anatomie der Taubstummheit. (*The Anatomy of Deaf-mutism.*) Published in the Proceedings of the German Otological Society. First part. Contents: I. SIEBENMANN, Malformations of the Ossicles and Fenestræ; Collapse of the Ductus Cochlearis, all three walls of which show signs of progressive dilatation. With five Figures in Tables I. and II. II. WATSUJI, Histological Researches on Deaf-mutism. With three Figures in Table III. III. POLITZER, The Anatomical Condition of the Organs of Hearing in a Deaf and Dumb Patient, with six Figures in Table IV. With four Tables. Wiesbaden: J. F. Bergmann. 1904. Pp. 20. Price 5s. 6d.

It appears that the inception of this work was due to some remarks made by Professor Arthur Hartmann of Berlin in 1903 at the German Otological Society, when he justly said that few had any knowledge of the auditory apparatus of deaf-mutes, and it was with a view to a more general extension and distribution of such knowledge that this book was published. It will be welcomed by all earnest students in

otology and pathology and it is much to be desired that a work of such importance should be rendered into English. In this, the first part, Professor Siebenmann, Dr. Watsuji, and Professor Politzer are the contributors.

Professor Siebenmann's contribution to this part consists in a detailed description of the pathological conditions found in the case of a man who died when 53 years of age. He had been born deaf although there was a slight appreciation of speech. On the left side the following macroscopical conditions were observed. The meatus and the drum were normal. In the middle ear the long process of the incus was of normal thickness and strength, exceeding the normal by 2 millimetres in length. The posterior limb of the stapes was firmly bound down by scar tissue and the capsule of the inco-stapedial joint was connected with the fibrous sheath of the facial nerve. The posterior limb of the stapes was thick and long, the capitulum was markedly stronger than usual, and the foot plate was much thickened. The articular cartilages were atrophied, with a tendency towards rarefaction of the ossicles and the round window was very much diminished in size. The labyrinth was particularly rich in pigment. There were numerous changes in the posterior half of the membranous labyrinth. The bony divisions in the cochlea were thin. In the upper part of the modiolus the bone was absent. The changes in the nervous apparatus were also of great importance but space does not admit of a full description. This case is illustrated by two plates consisting of five figures. The first is a section from the malleus and incus, showing thickening of the bones and the connexion between the long process of the incus, the stapes, and the sheath of the facial nerve. Fig. 2 is a micro-photograph of the cochlea, showing the want of development in the organ of Corti.

The histological study of deaf-mutism is the contribution by Dr. Watsuji. The preparations were made from the ears of a patient who died at the age of 41 years. This was a case in which it was impossible to determine from the patient's statements whether the defect was congenital or acquired. His wife was a deaf-mute but his children had normal hearing. In this case in both ears, with the exception of narrowing of one of the semicircular canals, the chief changes were found in the cochlea. The description is illustrated by three plates of exquisite workmanship.

Professor Politzer's contribution is quite short compared with the last mentioned. Here also the changes were most marked in the cochlea. The illustrations of microscopical sections in this instance are most beautiful.

The earliest work with which we are acquainted which is of really scientific value in connexion with this most abstruse and interesting abnormal condition is that by Mr. Cock, the well-known surgeon of Guy's Hospital, who made a large number of dissections in the early part of the last century. His contribution to the science was necessarily macroscopic but in all his cases the prominent feature was the non-development, or obstruction by bony growth, of the semicircular canals. This does not appear to have occurred or to have been noticed in these three cases and if it was not noticed by such observers we may justifiably assume that it did not exist.

It is, however, somewhat to be regretted that no very detailed description is given of the absolute state of hearing, or the remnant of hearing, with the exception of that by Dr. Watsuji, from which we learn that bone conduction for the watch was present but no vocal sound whatever was heard. There was a slight perception of Galton's whistle and the patient was able to hear C (of 128 vibrations) by bone conduction on the right side. This in itself is an extremely interesting observation, though the maximum of hearing, what may be termed the better ear was only seven seconds. Here we meet immediately with a difficulty, a difficulty

which meets us in all hearing tests, and that is, that the weight of the blow of any tuning fork is not a universal standard, and so we are in England no wiser than if the author had merely stated "perception of sound."

This work emphasises the high pitch of excellence to which otology has advanced amongst the German-speaking races and the freedom from petty jealousies which enables men of such world-wide repute to work together for the advancement of their specialty. The three authors are deserving of high praise; they have produced the first part of a series which, we are convinced, will form a standard on the subject.

The Vermiform Appendix and its Diseases. By HOWARD A. KELLY, A.B., M.D., Professor of Gynecology in the Johns Hopkins University, Baltimore; and E. HURDON, M.D., Assistant in Gynecology in the Johns Hopkins University, Baltimore. With 399 original illustrations, some in colour, and three lithographic plates. London and Philadelphia: W. B. Saunders and Co. 1905. Pp. 827. Price 42s. net.

WE think it will be long before any larger work than this on the appendix will appear. The volume before us has more than 800 pages and about half as many illustrations and we may add that it weighs some seven pounds. Clearly no exertion on the part of the authors and no expense on the part of the publishers have been spared to make this the fullest and most thorough work on the subject. No one can complain that the authors have taken too narrow a view of their task, for they have devoted more than 50 pages to the history of the subject. They have given nearly 150 pages to the anatomy of the appendix and the other departments of the subject have been equally generously treated. Even the medico-legal aspects of appendicitis have not been forgotten. To describe more particularly one division, we may mention the contents of the anatomical section. The embryology of the appendix is first described and numerous illustrations of the embryo are given at various ages from six weeks to seven months and a series of diagrams shows that the appendix is a retrogressive organ, as at first it is merely the distal portion of the caecum but fails to maintain the same degree of development as the rest of that portion of the colon, so that ultimately its calibre is far less. An account of the comparative anatomy of the caecum is then given and the authors show the enormous variations in form which occur even amongst the mammalia. Comparatively few animals are favoured with the possession of an appendix caecal and man is one of them. The next point of the anatomy dealt with comprises the peritoneal folds of the caecum and their importance is maintained. The variations of the meso-appendix are described and the varieties of the supplying arteries. The arrangement of the ileo-caecal region and its valves is also discussed. Then comes an account of the possible points of origin of the appendix and the directions which it may take. The very great variations in the position of the appendix are often of the greatest importance to the surgeon. The length and the structure of the organ, both naked eye and microscopical, are fully dealt with. The accounts of the blood-supply, the lymphatics, and the nerves occupy a chapter to themselves.

We have said enough to indicate the very elaborate scale on which the book is written and we may add that the authors are careful to give credit to whom it is due. Quotations from other writers are freely given and in many cases these are in the original language in which they were written. We have nothing but praise for the work as a whole; here and there there are points where we might feel inclined to differ from the views expressed by the authors but in nearly every portion of the subject opinion is in a state of flux and the views held to-day may differ widely from those prevalent to-morrow. The work is especially suited to physicians or surgeons who wish to have in one

volume the essence of all that has ever been written about the appendix, and though it is too voluminous for the busy general practitioner yet anyone who can spare the time even to dip into its pages will find himself well repaid by the pleasant style and the interesting facts therein contained. The authors evidently contemplate a second edition as they tell us that it will contain a fuller account of leucocytosis in relation to appendicitis.

The Book of Prescriptions (Beasley) with an Index of Diseases and Remedies. Rewritten by E. W. LUCAS, F.I.C., F.C.S., late Examiner to the Pharmaceutical Society of Great Britain. With an introduction by ARTHUR O. LATHAM, M.A., M.D. Oxon., F.R.C.P. Lond., Senior Assistant Physician at St. George's Hospital and Assistant Physician at the Brompton Hospital for Consumption. Eighth edition. London: J. and A. Churchill. 1905. Pp. 366. Price 5s.

THE fact that this publication has reached an eighth edition is sufficient proof that it has been duly appreciated. The book contains an excellent series of prescriptions illustrating the employment of the materia medica in general use. It also comprises notes on the pharmacology and therapeutics of the principal drugs and the doses of their preparations. The quantities of the various medicaments employed are expressed according to the imperial system, but the practical equivalents according to the metric system are also given.

As Dr. Latham states in the introduction, medical students of the present day have seldom mastered the difficult art of prescribing at the time at which they obtain their qualification to practise. In consequence of this defect in the medical training the qualified man starts on his career imperfectly informed in a necessary part of his professional duties. He has to learn laboriously when his opportunities may be few and in certain instances he may be tempted to rely too much on various proprietary mixtures. Further, whilst in hospital he generally sees prescriptions written according to certain titles, such as "haust. gent. alk.," "haust. ferri c. mag.," but if questioned as to the ingredients of such mixtures he may fail to give a correct answer. A work of the kind that we are considering, if properly used, helps to remedy such defects, and a study of the numerous prescriptions which are given should prove of the greatest service to the young practitioner. Every drug in common use is included in the present edition; in considering each one the physical and chemical characteristics of the various preparations are mentioned. The therapeutical and medicinal values are precisely indicated and the doses, as we have already remarked, are stated according to both the imperial and the metric systems. The various prescriptions are accurate and trustworthy. We can recommend this manual to senior students and practitioners as a useful adjunct to the ordinary text-books on medicine.

Report on Sanitary Measures in India in 1903-04. Vol. XXXVII. London: Printed for His Majesty's Stationery Office by Darling and Son. 1905. Pp. 203. Price 1s. 8d.

THIS report is prepared for presentation to Parliament. It contains chapters on the health of the European and native troops, on the health of prisoners in jails, and on the health of the general population; it also contains chapters on vaccination, on medical institutions, including medical schools and lunatic asylums, and a chapter on sanitary works. Appended to the report are abstracts of reports by the principal Sanitary Commissioners in India and memoranda by the Army Sanitary Commission in England reviewing the several sanitary reports for India. The report shows that there was a marked improvement in the health of the European troops serving in India during the year 1903; the daily sick and invaliding rates were much lower than in the previous year and the death-rate improved.

On an average strength of 70,445 the admissions into hospital were in the ratio of 1033 per 1000, against 1078 in 1902; the daily sick-rate fell from 66 to 63. The invaliding ratio (29) was lower by 8 per 1000, so that the total loss by death and invaliding was equal to 42 per 1000, a decrease of 10 per 1000 on the previous year. Madras and Burma had the highest sick-rates and Bengal and Burma the highest death-rates. The chief causes of sickness in the whole European army were venereal diseases and ague; the former yielding a ratio of 247 per 1000 against 281 in 1902 and the latter 243 per 1000 against 247. 47 per cent. of the total sickness resulted from these two causes. Enteric fever, as usual, was the chief cause of mortality, the death-rate being slightly lower than the ratio of the previous year. Cholera was very prevalent and among the European troops 81 cases were recorded with 57 deaths. Among the European troops in India there were during the year 68 cases of small-pox with eight deaths. Enteric fever was more prevalent than in the previous year. There were 12 cases of plague among the European troops and two deaths. Venereal diseases ranked first in the list of causes of admission to hospital and first in the causes of invaliding. They were the cause of nearly 24 per cent. of the total sickness during 1903 and of 10½ per cent. of the invaliding of the European army. Venereal diseases were ten times more prevalent among the European troops than among their comrades of the native army. The Gurkhas invariably suffer in a much higher degree than the rest of the native troops.

The health of the native army during 1903 was exceptionally good. The admission and constantly sick rates were the lowest on record and the death-rate was lower than in any previous year. The chief cause of sickness in the native army was ague. Pneumonia was, as usual, the chief cause of death. From cholera there were 80 deaths in the native army and there were 184 cases of plague with 115 deaths. As regards the general population, the health of the people was less satisfactory chiefly owing to the prevalence of cholera and plague. Malarial fever was less prevalent than in the preceding year, but nearly twice as many deaths were recorded from plague as in 1902. The Punjab was the unhealthiest province in India in 1903. The health statistics of the jails show a further satisfactory improvement in the health of the prisoners. Vaccination is steadily being advanced, there being an increase of 25,734 operations on the number of the previous year. With regard to sanitation, in Calcutta substantial progress was made during the year in ridding the city of many objectionable and insanitary collections of native huts, resulting in the opening up of many unhealthy areas by the construction of public squares. In the Punjab good progress was made during the year in the important works which have been undertaken for the improvement of the sanitation of Simla and in the waterworks of Aurlitsar city. In Madras city progress was made with the new drainage scheme and in Bombay city progress was made with the special drainage works. In the report the question of the prophylaxis of malarial fevers is discussed as a whole in "General Remarks" (p. 122). There can be no doubt that the efforts put forth during the year under notice have been far more general, more complete, more consistently and energetically maintained, and better organised than heretofore. At the same time, signs are not wanting that in many respects the work of prophylaxis has yet to be developed in its range and in completeness before measurable results can be hoped for.

LIBRARY TABLE.

The Source of the Blue Nile. By ARTHUR J. HAYES, L.S.A. Lond. London: Smith, Elder, and Co. 1905. Pp. 315. Price 10s. 6d. net.—Mr. Hayes was the medical

officer of a survey party which was despatched to make observations as to the annual rise of the Blue Nile in connexion with the works for the great Assuan dam. The Blue Nile rises in Lake Tsana which is in Abyssinia. Thither Mr. Hayes and his companions wended their way, starting from Khartoum and returning by way of the Atbara valley. Mr. Hayes has written a pleasant and chatty description of the expedition. He is evidently not an experienced traveller but he is observant. Thus he notes with somewhat naive astonishment (p. 61) some ordinary "pot holes" in the bed of the Geerar river. Where his own information or knowledge is deficient he supplements it in modest and praiseworthy fashion from that gathered by other travellers. With these qualifications Mr. Hayes should one day produce a book of value if his lot should again lead him into out-of-the-way places. With regard to the vexed question as to whether birds of prey, especially vultures, are attracted by sight or smell, Mr. Hayes says that his observations agree with those of Sir Samuel Baker, from whose book, "The Nile Tributaries of Abyssinia," he gives a long quotation. Baker thought that sight was the sense which played the principal part. Readers of Waterton's delightful essays will recollect that that eminent but obstinate traveller came to exactly the opposite conclusion in his controversy with Audubon. In THE LANCET of Sept. 9th, 1899, we commented, under the heading of "An African Mystery," upon a curious experience undergone by Captain Welby, whose early death was a great loss to scientific geography. Welby was travelling through the Walamo country which lies to the south of Adis Abeba which again lies some way to the south of Lake Tsana. A curious kind of demoniacal possession afflicted those who travelled in the country and this was specially prone to happen if the traveller took any food while the Walamo were looking at him. Welby as an avowed disbeliever tried the experiment and the next day he says "I felt thoroughly ill." Mr. Hayes came across a somewhat similar belief at the village of Bahrdar Georgis (St. George is a famous saint in Abyssinia), which lies just at the exit of the Blue Nile from the lake. In this village any person of rank is carefully shielded from view while he eats or drinks in order to protect him from the evil eye. The book is illustrated with excellent reproductions of photographs and has an appendix containing a note upon the religion and customs of Abyssinia, the information in which has been mainly collated from the works of previous travellers. An interesting description is given of a disease allied to demoniacal possession which is known by the name of *bonda*. Altogether the book is well worth reading but we hope that when the next edition appears an index will be provided.

A Guide to Diabetic Cookery. Published by Callard and Co. Price 1s.—To arrange a suitable diet table for a diabetic patient which shall offer sufficient variety to tempt the appetite while not transgressing the limits laid down by the physician needs a considerable knowledge of cookery as well as of medicine. This little book should prove very useful to those who have to undertake the management of such a case. A large variety of recipes are given, embracing soups, meats and savouries, puddings, and so on, all made from ingredients which are permitted to diabetic patients. Some doubt may perhaps arise as to the advisability of using any considerable quantities of glycerine for diabetic cookery in view of Luthje's experiments, but probably the small amounts necessary for sweetening would do no harm in ordinary cases.

On Active Service with the St. John Ambulance Brigade (South African War, 1899-1902). By the late WILLIAM B. INDER. Demy 8vo, with 25 illustrations. London: Dale, Reynolds, and Co. 1905. Pp. 318. Price 5s.—The author of this book was the late Sergeant W. S. Inder of the Kendal

Division of the St. John Ambulance Brigade. The chief attraction of the volume is the clear account of many of the chief incidents of the South African campaign, but the book contains much good-humoured gossip about the St. John Ambulance Brigade, Scottish Horse, and Active Service Volunteers which will be read by many with considerable pleasure. It is a brightly written narrative of a faithful man's work and it brings the scenes passed through vividly before the reader. The sketches of scenes among the field hospitals afford realistic pictures of the medical side of the war. The author went out to South Africa in December, 1899, on the s.s. *Simla*, and landed in time to help to look after the wounded Highlanders after Magersfontein. He was evidently a keen and capable ambulance man, deservedly popular with all the staff, and his diary is written with a literary skill much above the average. Throughout the book we are brought face to face with a kind, sympathetic, and loveable nature, and we realise that it was such men as he who made the St. John Ambulance orderly so much appreciated in South Africa. We recommend the book to the notice of those who are interested in the history of the war and specially to those who work for the St. John Ambulance Association.

The Nursing of Sick Children. By JAMES BURNET, M.D. Edin., M.B.C.P. Edin., Registrar and Assistant to the Extra-Physicians, Royal Hospital for Sick Children, Edinburgh. London: The Scientific Press 1905. Pp. 66. Price 1s net.—These pages are intended to serve merely as an introduction to this subject. The author hopes that a careful perusal of this handbook will supply to a certain extent the want of special training in children's ailments in nurses who have had but little opportunity afforded them of acquiring a knowledge in children's wards. Nurses, however, who are devoting their attention specially to children will doubtless find the information contained in this book helpful. The recommendations are quite sound; they are at the same time simple and capable of being easily understood. The information has evidently been carefully put together, the directions are explicit, and but little is left to the nurse's imagination. We regard it as a helpful little manual.

Guy's Hospital Nursing Guide: Handbook of Nurses' League and Register of Nurses Trained at Guy's Hospital. Third issue. London: Ash and Co. 1905. Pp. 150. Price 1s 6d.—The original object in view in the preparation of this work was simply to provide a handbook of the Nurses' League of Guy's Hospital and a register of the nurses trained at that institution. In the course of preparation the desirability was recognised of including a section which would be of general service to the community. The first part of the book contains a nursing guide which we can recommend as a trustworthy source of information to those who are thinking of entering upon the work of nursing. Those who are attracted to this work will here find advice and knowledge which will enable them to form a just opinion of what is before them during their careers. The register of the nurses is as useful and comprehensive as in the former issues of this book.

Cattle Tuberculosis. By HAROLD SESSIONS, F.R.C.V.S., F.H.A.S., F.R.G.S. Second edition. London: Baillière, Tindall, and Cox. 1905. Pp. 130. Price 2s. net.—This brochure is intended as a practical guide to the agriculturist and meat inspector and quite fulfils its object, as it gives in a concise and practical manner an up-to-date aspect of the latest theories and practical facts in connexion with tuberculosis in cattle. It is a little book which we can thoroughly recommend to the favourable notice not only of the practitioner but of every medical officer of health. It deals thoroughly with the cases of tuberculosis, not only of cattle but of the human being, and one chapter is devoted to a comparison between human tuberculosis and that of bovine, statistics

being given in tabular form to illustrate various points. The origin of the disease, the symptoms and diagnosis, and the use of tuberculin as a means of detection and prevention are clearly discussed, as are also the regulations dealing with milk and meat. In the chapter on the disposal of affected carcasses Mr. Sessions quotes the methods which are employed in foreign countries and particularly lays stress on the sterilisation method which is so satisfactorily carried out on the continent. The book is well got up and we are sure that it will find a ready sale.

The Animal Parasites of Man. By Dr. MAX BRAUN. Third edition, with 234 illustrations. Translated by PAULINE FALCKE and brought up to date by LOUIS SAMBON, M.D., Naples, and FRED. V. THEOBALD, M.A. London: Bale, Sons, and Daniellson. 1906. Pp. 453. Price 21s. net.—Braun's work on human parasites is well known in Germany, in which country it has reached a third edition, and the translators have certainly done a service to the English-speaking profession in bringing it within the reach of all in this country who are interested in parasitology. In the present day the study of parasites has become such an essential feature, especially to those whose work takes them to tropical countries, that it might almost be said to have become a specialised science. It would be almost invidious to pick out any particular chapter as all are of the utmost interest, but we may legitimately be pardoned for particularly drawing attention to the illustrations and descriptions of the mosquito. However, every part of the book is full of interest and it quite fulfils the purpose for which it is said to be destined—viz., a handbook for students and medical men.

Essentials of Physiology for Veterinary Students. By D. NOEL PATON, M.D., B.Sc. Edin., F.R.C.P. Edin. Illustrated. Edinburgh: William Green and Sons. 1905. Pp. 428.—There are many points of difference between the physiology of man and of lower animals and it is quite necessary that the veterinary student should be taught specially and not be allowed to gain his knowledge merely from a medical textbook. Dr. Paton, who at one time occupied the chair of physiology in the Royal Veterinary College, Edinburgh, and who is at the present time one of the examiners of the Royal College of Veterinary Surgeons, has endeavoured in as concise a manner as possible to place together the essentials of the general and special physiology of the domesticated animals in a form suitable to the requirements of students and practitioners of veterinary medicine. The general aspect of physiology is deeply entered into and no efforts are left undone to make it easily understandable and complete, and the special aspect, as it applies to the various domesticated animals, has been touched upon, although not quite so fully perhaps as the student of veterinary physiology could have desired. Many of the plates, too, are of the human organs and would be better if taken from the animals themselves, but probably this side will receive more attention when the book reaches, as we are sure it will, a second edition. The book is a useful one and will form a welcome addition to the veterinary student's library.

JOURNALS AND MAGAZINES.

The Edinburgh Medical Journal.—This magazine opens the new year with an excellent number. It contains two articles of interest upon the tuberculosis question—one by Dr. R. W. Philip on the Erection of Municipal Dispensaries and another by Dr. John Robertson on Prevention of the Disease by Means of Notification along with the provision of sanatoriums and homes for consumptives. A preliminary communication by Dr. J. Eason deals with the pathology of paroxysmal hæmoglobinuria and attributes the phenomena of this condition to the presence of a special hæmolytic amoceptor in the serum. Mr. H. Alexis Thomson records the notes of four cases—three of malignant disease and one

which subsequently proved to be a papilloma—treated with Doyen's serum, apparently without good results. Mr. H. Harvey Littlejohn and Mr. T. W. Drinkwater deal with poisoning with arsenious acid, calling attention to the occurrence of yellow sulphide of arsenic in the alimentary canal.

The Scottish Medical and Surgical Journal (January).—Professor John Chiene, the retiring president of the Medico-Chirurgical Society of Edinburgh, in a valedictory address deals with the history of the society during the past 50 years. Dr. B. P. Watson publishes the results of some experiments on rabbits to elucidate the effects of withdrawal of the liquor amnii, which is followed by death of the fœtus and degenerative changes in the placenta; the latter closely correspond with those described by Eden in the retained human placenta. Dr. David H. Stirling gives some statistics of results obtained at a sanatorium for tuberculosis and Mr. H. M. W. Gray comments on a variety of surgical conditions, especially dealing with the use of vaccines in surgical cases.

The West London Medical Journal (January).—This number opens with two short papers on climatic subjects, the first by Dr. S. A. Bontor dealing with Jamaica as a Health Resort and the second by Dr. W. S. Colman with some French Health Resorts. Dr. A. P. Beddard gives an account of recent work on the Opsonic Powers of the Blood and manages to make this rather difficult matter intelligible to those who have not previously studied the question. Dr. D. G. A. Chowry-Muthu sets forth his belief that static electricity is of value in the treatment of pulmonary tuberculosis.

The Medical Chronicle (December, 1905).—In this number Professor W. Stirling's article on Coöperation and Adaptation in Digestion is concluded. The second part deals with modern work and points out the two kinds of stimuli which give rise to secretion of digestive juices, the hormones or chemical excitants acting slowly and continuously, and the nervous impulses acting quickly. Mr. E. D. Telford records a case of Umbilical Hernia in which perforation of the small intestine in the sac was caused by the presence of a piece of rabbit's bone.

New Inventions.

THE EQUIPOISE BED, COUCH, AND CARRYING CHAIR.

At the Institute of Hygiene, 34, Devonshire-street, London, W., a bed of ingenious construction is on exhibition, which has been brought out by the Equipose Couch Co., Ashford, Kent. The mechanism is that of a ratchet wheel and pawl with crank-handle attachment, enabling the top part of the bed to be manipulated and fixed at any angle required. When the desired position has been reached it can be there retained for so long a time as is necessary. The mechanism works so smoothly that the position of the patient's head and shoulders, however helpless or heavy he may be, can be changed as often as wished for and without the slightest difficulty by the nurse or attendant. If the patient is able to use his arms he can easily adjust himself to whatever position he wishes with the smallest possible exertion. If, on the other hand, he is suffering from acute heart disease or from a malady in which any exertion is dangerous the nurse can alter his posture so easily that he is scarcely conscious of movement. Another advantage claimed for the bed is that the bottom can be dropped, an arrangement which provides a double inclined plane, thus affording relief to the thighs and the legs. The bed is intended for the use of invalids and should serve its purpose well. The illustrations represent two of the many positions which may be given to the bed. The price is five and a half guineas. It may be upholstered in imitation leather, tapestry, or morocco at an additional charge, and handles are supplied for use when the bed is carried about with a patient lying on it. Chairs, couches, and surgery

FIG. 1.

FIG. 2.

chairs are constructed by the Equipose Co. upon the same principle but none of these were on exhibition.

AN ASEPTIC EAR OR WOUND SYRINGE.

THE defect of most piston and other syringes which are filled through the nozzle is the great difficulty of keeping them "surgically" clean. The instrument shown in the illustration, however, since its parts are made entirely of metal and readily separated, can be easily sterilised. Further, its makers have, at my suggestion, added a nozzle which, being detachable, not only enables the syringe to be filled without risk of contaminating its interior through an infected aperture but also facilitates the cleaning of the nozzle itself, precautions of the utmost importance in aural treatment. In use the syringe is filled with fluid through the fixed nozzle, after which the detachable nozzle shown at the side is slipped over the fixed one and the fluid is ejected in the ordinary way. Before refilling the syringe or proceeding to the other ear or to the next patient the detachable nozzle is removed and cleansed. A convenient length for these nozzles is four inches; it will sometimes be advantageous to have more than one of them. The syringe may be had in sizes of one, two, three, and four ounces. It is made by the Medical Supply Association of 228, Gray's Inn-road, London, W.C., with nozzles of various sizes.

THE LANCET.

LONDON: SATURDAY, JANUARY 27, 1906

The Value of the Tuberculo-opsonic Index in the Diagnosis and Treatment of Tuberculous Infections.

THE Royal Medical and Chirurgical Society is to be congratulated upon the success of a recent discussion of the vaccine treatment of tuberculous infections.¹ The convening of symposial meetings for the consideration of the work of different observers, who are attacking the problems of a given disease along similar lines but from different standpoints, frequently affords valuable assistance alike to the investigators themselves and to the profession of medicine in general. The former often receive useful suggestions and encouragement in their work, while the practitioner may be enabled to extend his usefulness or to improve his mode of procedure by the adoption of the advances which may be thus established. The present time is an appropriate one to consider the value of the attempts to produce a specific cure for tuberculosis. The various anti-tuberculous sera hitherto introduced have given at best but disappointing results and Dr. W. BULLOCK² in his paper read at the above-mentioned meeting was inclined to regard the era of tuberculous serotherapy as past. There is, on the other hand, at present a disposition to return to the use of some vaccine; in other words, to revert to the method originally introduced by KOCH, for it should be borne in mind that all the forms of tuberculin and its many derivatives are technically vaccines—i.e., dissolved or suspended substances derived from the bacilli. This method has been consistently defended and modified by him and adopted with some measure of success by TRUDEAU, POTTENGER, TURBAN, PETRUSKEY, and other observers. TRUDEAU's conclusions are of special interest, since as a result of observation of a series of cases extending over 12 years he found that the inoculation of tuberculin used as an adjunct to sanatorium treatment gave a larger percentage of "cures" and a smaller percentage of relapses than sanatorium treatment alone. In this country tuberculin after the first disappointment at its results fell into disrepute, and both it and its successors have been but little used. But the illuminating and exact researches of Professor A. E. WRIGHT have demonstrated the value of the method of treatment by tuberculous vaccines and have afforded an index by which to gauge the effect of the inoculations and to determine the times at which they should be given.

The discovery of opsonins and the investigation of the opsonic index are of such importance that we

may perhaps be pardoned if, assuming that not all of our readers are familiar with them, we briefly outline the principles and technique of Professor WRIGHT's researches. The study of immunity and of the reactions in the body produced by bacterial invasions has established the fact that the protective mechanism is a complex one, involving both the chemical agencies of certain antibacterial substances in the serum and tissue fluids and the vital activities of the phagocytes. The protective substances exert their influence by combining with the chemical constituents of the bacteria and are therefore called bacteriotropic substances by KOCH. According to the effect which they produce they are called agglutinins, bactericidal substances, bacteriolyins, or opsonins. The opsonins apparently prepare the bacteria for ingestion by the phagocytes, since if normal white corpuscles be washed with isotonic salt solutions so as to get rid of the serum the corpuscles will no longer ingest bacteria, but they will do so at once in the presence of normal serum. The opsonic index for a given organism is the ratio of the opsonic power of the serum to be tested to that of a normal person. This is determined by taking in a capillary tube equal quantities of washed blood corpuscles, of a suspension of tubercle bacilli, and of the serum to be tested, mixing them and incubating for about 20 minutes, and then determining the average number of bacilli ingested per corpuscle. Precisely the same determination is made with a normal serum or the mixed serum of several normal persons. The ratio of the two numbers obtained gives the opsonic index of the first serum. The tuberculo-opsonic index in healthy persons seems to be very constant; thus in various series recorded independently by Dr. BULLOCK, by Dr. DAVID LAWSON and Dr. I. S. STEWART, and by Dr. G. W. ROSS the opsonic index found in healthy persons was always between 0.8 and 1.2, giving a mean of 0.95. In tuberculous subjects, on the other hand, very considerable variations are found. Professor WRIGHT maintains, and all the above observers support his contention, that an index beyond the normal range—i.e., below 0.8 or above 1.2—is strongly suggestive of the presence of tuberculosis. Dr. ROSS, indeed, has stated that he had never found an opsonic index of 1.3 in any case that was not definitely tuberculous. On the other hand, in 75 per cent. of his cases of lupus Dr. BULLOCK found an opsonic index below the lowest normal limit of 0.8. These apparently paradoxical results find a very plausible explanation in the observations of Professor WRIGHT who maintains that two classes of bacterial invasions exist, in one of which—the local infections—the opsonic power remains permanently low and does not vary, while in the other class—the systemic infections—it fluctuates and is frequently above the normal. In the former the mechanism of protection is not set into action owing to the local character of the infection and the rarity with which bacteria or their products reach the general circulation, whereas the variations of the index in the general infections are due to auto-inoculations of bacterial elements. When the effect of an injection of a vaccine is considered it is found that the first result is invariably a diminution in the protective substances, as shown by a lessening of the opsonic power. This is referred to as the "negative phase" and is followed by an increase of the protective power

¹ THE LANCET, Dec. 2nd and 9th and 16th, 1905.

² THE LANCET, Dec. 2nd, 1905, p. 1603.

and a rise in the opsonic index beyond the original height, constituting the "positive phase." This increased height may be maintained but in the case of tubercle vaccines it usually comes down to its original level. Professor WRIGHT finds that negative phases can be superimposed if successive inoculations succeed one another too rapidly, thus lowering the patient's resistance and producing injurious effects, whereas it is difficult in the case of tubercle vaccines to obtain cumulation of positive phases. He has by this means explained the variable and disappointing results obtained with tuberculin by some observers, while he maintains that the determination of the opsonic index is an indispensable guide to the administration of successive doses and to the quantity to be given. For example, if with successive doses the negative phase becomes less marked the dose is adequate and is beneficial, whereas if the negative phases become more marked the dose must be lessened. It is obvious that an injection should never be given during a negative phase. Moreover, small doses are quite effective in starting the formation of protective substances and, doubtless, in the past far too large doses have been given. Professor WRIGHT now uses the new tuberculin (T.R.) of KOCH in quantities equal to $\frac{1}{100}$ th milligramme of dried powdered bacillary substance and never exceeds $\frac{1}{50}$ th milligramme.

A criticism of Professor WRIGHT's views by Mr. W. WATSON CHEYNE appeared in our columns shortly after the publication of the papers read at the Royal Medical and Chirurgical Society.³ Mr. WATSON CHEYNE, while recognising the originality and the brilliance of the work, regards many of Professor WRIGHT's contentions as theoretical and not proven, and deprecates any intemperance in applying the principles of inoculation to the exclusion of other well-tried methods, both surgical and hygienic, as likely to lead to disappointment and once again to cast discredit on tuberculin as a remedy. He thinks that other as yet incompletely elucidated factors in the production and spread of local bacterial diseases will have to be taken into consideration and that therefore an exaggeration of the importance of the opsonic factor in the protective mechanism may tend to hinder rather than to promote progress. The warning is a sound one. When the outcome of such inoculations is considered it is found that in localised tuberculous lesions satisfactory results have been obtained, especially when measures have been simultaneously adopted to increase the flow of lymph through the affected part. Examples of such localised lesions as lupus, tuberculous ulceration of subcutaneous tissues and bone, tuberculous glands, genito-urinary tuberculosis, tuberculosis of joints and of the peritoneum, and pulmonary tuberculosis without fever, have all exhibited benefit when so treated. On the other hand, in general infections the problems are much more complex and the fact that bacterial products are being spontaneously absorbed renders the administration of further bacterial substances a doubtful expedient. Professor WRIGHT suggests that before doing so we must prevent the auto-inoculations and thus endeavour to convert the infection into a localised one, and considers that for this purpose the

patient should be kept at rest in bed and the coagulability of the blood increased in order to lessen lymph flow and then later, when this is effected, carefully controlled and interspaced doses of vaccine should be administered. At present, however, it would seem that, at any rate as regards cases of pulmonary tuberculosis, the method is only likely to be of value in apyrexial cases in which the painstaking, laborious, and carefully recorded observations of Dr. LAWSON and Dr. STEWART point to a beneficial effect, for they found that the protective power of such cases in sanatoriums could be raised by inoculations to a higher level than is possible by sanatorium or climatic treatment alone, and in this their results coincide with those of TRUDEAU. There are difficulties in the way of any general adoption of the method, since the determination of the opsonic index requires considerable practice and makes large demands on the time of the investigator if any number of cases is concerned. Dr. LAWSON and Dr. STEWART endeavoured to find some more easily observed clinical manifestation of the negative phase but without success, so that at present the opsonic index is for most conditions indispensable. In a series of cases of tuberculosis of the urinary system, incorporated in a paper by Mr. J. G. PARDOE⁴ read at the same meeting of the Royal Medical and Chirurgical Society, the inoculations of tuberculin (T.R.) were given without determination of the opsonic index, as symptoms are quickly produced in these cases by overdosing which are easily recognisable. If some less laborious means of estimating the protective power and its variations can be discovered for other conditions the usefulness of the method will be greatly extended.

Stokes-Adams Disease due to a Lesion of the Auriculo-Ventricular Bundle of His.

FEW diseases offer such a field for the application of known physiological principles to pathological phenomena as that to which the name of Stokes-Adams disease has been applied. The striking character of its symptoms—slow pulse with syncope, apoplecticiform, or epilepticiform attacks, and the associated phenomena of Cheyne-Stokes breathing, angina pectoris, and cardiac arrest—combines to give it a peculiar interest. An excellent historical and critical survey of our knowledge of this disease by Professor W. OSLER was published in THE LANCET of August 22nd, 1903.

Recently in an annotation¹ we drew attention to some interesting experiments by Dr. JOSEPH ERLANGER on the phenomenon termed "heart block" by physiologists, which threw light on Stokes-Adams disease. In studying a case of the disease he found that the bradycardia was due to heart block. When the block was complete the auricles responded normally to influences exerted on the heart through its extrinsic nerves but the ventricles did not respond. This led Dr. ERLANGER to study heart block by experiments on a dog. He found that on clamping the limited region in which lies the

⁴ THE LANCET, Dec. 16th, 1905, p. 1766.
¹ THE LANCET, July 29th, 1906, p. 306.

only muscular connexion between the auricles and ventricles (the auriculo-ventricular bundle of His) the normal sequence of auricular and ventricular beats gave place to a partial block in which the beats of the auricles were to those of the ventricles as 2 to 1. On further clamping the ratio rose to 3 to 1 and this condition usually passed into one of complete block in which the auricles and ventricles beat independently. The analogies with Stokes-Adams disease are obvious and led Dr. ERLANGER to conclude that the lesion is in the same position in both conditions. In the *American Journal of the Medical Sciences* for December, 1905, Dr. ALFRED STENGEL has published an interesting confirmation of Dr. ERLANGER's conclusion—the first case in which a lesion of the auriculo-ventricular bundle of His has been recorded. A man, aged 57 years, was admitted into hospital on Sept. 19th, 1905. His illness began two and a half years before; while working he suddenly fell back and became unconscious for a few moments. He speedily recovered but three months later had another attack and then attacks followed at the rate of one in every two or three weeks. The patient was well nourished. The arteries were atheromatous and the pulse was 36 and of slightly increased tension. There was pulsation in the epigastrium and in the veins of the neck. The apex beat was strong and visible in the fifth space just outside the mid-clavicular line where a systolic thrill was felt. A harsh systolic murmur was heard at the apex and transmitted to the axilla. The urine did not contain albumin but there were a few hyaline and granular casts. Attacks occurred on the 23rd; they began with momentary pallor which was followed by flushing or cyanosis and slight tremor of the arms. After the attack the face was pale and the colour gradually returned. During several of the attacks the pulse stopped for a few seconds. After the attack the pulse-rate increased for a short time and then subsided to a steady rate of 16 to 18. The pulsation of the veins of the neck continued during the attacks at the same rate as between them—80 to 100 a minute. During the attacks there was only partial unconsciousness. The attacks became more severe and more frequent. During one, which occurred on the morning of the 27th, the pulse stopped for two minutes and ten seconds. In the afternoon the attacks ceased but Cheyne-Stokes respiration began. Three hours later death occurred. During the last few days of life there was apparently complete heart block. The auricular (venous) pulsations were from 80 to 140 per minute while the ventricular pulsations were from 18 to 26. The former rate was maintained even while the pulse ceased during the attacks. In the intervals the pulse was fairly regular and strong, the rate being from 18 to 30. The necropsy showed hypertrophy of the heart, especially of the left ventricle. The muscle was of normal appearance except a small area at the upper part of the interventricular septum. The root of the aorta and the orifices of the coronary arteries were atheromatous. The coronary arteries were thickened but nowhere calcareous or stenotic. On the anterior leaflet of the mitral valve was an atheromatous patch, sclerotic and white, which extended to the endocardium exactly over the bundle of His where the latter passes from auricle to ventricle. The bundle was involved in the disease, the exact extent of which cannot

be stated until the microscopical examination is completed.

The phenomenon of "heart-block" has long been known to physiologists—indeed, since the classical experiments of STANNIUS on the frog's heart—although their explanation as the consequence of interference with the normal conduction of the wave of contraction is more recent. The application of these results to the explanation of the clinical features of cases of cardiac disease has, however, been much neglected. The interesting paper by Dr. JOHN HAY, which we published in last week's issue, shows how strikingly valuable such a study of the known physiological properties of heart muscle may be when applied to the peculiar and varying conditions of a complex case of cardio-vascular disease. Dr. HAY'S ingenious and careful comparison of the radial and the jugular pulses suggests that a disturbance of rhythm may be caused at one time by a block in the conductivity of the heart muscle and at another by a disturbance in its excitability. The method is one which would seem to offer a useful field in its application to other cases of cardiac irregularity by affording valuable indications for treatment. In this connexion it is of interest to note that STOKES in one of his original cases noted the peculiar character of the jugular pulsation and also that it was more than double the rate of the ventricular beat.

Barmaids.

A PAMPHLET on the employment of "Women as Barmaids" seems likely, at the first glance, to excite attention chiefly by the absurdity of its title, as displayed by the manifest impossibility of employing "men" in this particular capacity, however much they might be available as barman, or, in transatlantic phraseology, as "bar-tenders." But a total absence of any sense of humour is not a new feature of philanthropy and does not of necessity detract from the value of its work. On this particular occasion the pamphlet, notwithstanding its title, really contains matter worthy of consideration; and, notwithstanding the well-understood objections to restrictive legislation in general, makes out a case for prohibition which at least requires a reply. There can be no doubt in the mind of any reasonable person that the vocation of a barmaid is attended by perils from which young women should, so far as possible, be sheltered. We have lately published articles on the public-house as a factor in the spread of disease, and it is manifest that the conditions favourable to the diffusion of tuberculosis which those articles described must operate with far greater intensity upon the attendants, who are constantly exposed to them, than upon the customers, who come and go. But, even apart from these conditions, the long hours of standing and the frequently excessive fatigue are productive of many uterine and digestive disorders and of feelings of malaise which are only too likely to lead to the alcoholic indulgence for which many opportunities are afforded; while the male frequenters of a drinking bar are often persons of loose conversation and degraded character, the worst possible companions for girls and the most likely to lead them astray. If we add to this the consideration that the

employment affords no prospects; that it uses up the majority of those engaged in it as soon as the first attractiveness of youth is past; that it is followed by a small proportion only of the great body of women workers; and that the inscription over the gate of the Inferno is not inappropriate to it in relation to the difficulty of turning away to better forms of industry, we shall have stated a very strong case against the usages which permit young women thus to be occupied. It appears to be true that "learning the bar" has no tendency to render a woman a better wife or mother, that it affords her no security of employment after about the age of 30, that it renders her unacceptable to employers of almost every other kind, that it often permanently injures her health, and that it exposes her to exceptional risks of seduction and of intemperance, with the consequences, both to herself and to her offspring, which these conditions may entail. If this be so, we may well ask ourselves whether it is consistent with a due regard to the national welfare to allow the daughters of the Empire to be offered up as sacrifices to the Moloch of the drink traffic, or, as too often happens, to be employed as decoys for the purpose of adding to the intemperance by which the country is at once weakened and disgraced. The demand for the most perfect individual liberty compatible with the general welfare is a right and reasonable one; but it is not either right or reasonable that this liberty should extend so far as to allow young women, the majority of them of exceptionally good physique and appearance, and the best calculated among their contemporaries to be the mothers of healthy and vigorous children, to engage in an avocation which is not only likely to be highly injurious to themselves but which is almost certain to prevent the full discharge of their duties to the community.

It may perhaps be fairly questioned by any who are acquainted with the conditions of industrial life to-day and with the nature of the industrial and moral training commonly afforded either by the schools of the period or by the majority of working-class mothers, whether the girls and women who are growing up around us might not profitably be subjected to a larger measure of supervision than is ordinarily extended to them. On every side it is manifest that the great desire of the working-class girl is to be "independent" of home or of every other control, while at the same time there has usually been but little preparation in her past to enable her to exert her independence for her own permanent advantage. Domestic service with a careful mistress, usually at once the best protection for the inexperience of youth and the best possible preparation for the duties of wifehood and maternity, is falling more and more into disfavour with the classes for whom it was once almost the sole means of remunerative employment, and, where it is still adopted, is to a large extent regarded on both sides as a mere contract for work and wages, involving no reciprocity of duty beyond the performance of the former and the payment of the latter. The modern very considerable development in London and large provincial towns of ladies' clubs, of tea-rooms, and of such-like establishments, in which waitresses are only required during certain portions of the day, has greatly tended to encourage discontent with ordinary

household duties and with the restraints inseparable from them, and although the openings of the new kind are not yet sufficiently numerous to affect materially the great mass of female labour, they are undoubtedly sufficient to occasion general discontent with all positions in which similar restraints are unavoidable. It would seem to dispassionate observers that in these social matters, as well as in regard to many public questions, the members of the working classes, of both sexes, have been placed in positions of greater liberty and greater independence than they are at present qualified to fill with advantage either to themselves or to the community, and that we may possibly have to pay a heavy national reckoning for their mistakes. If we should be spared this reckoning, our people may be expected by-and-by to have learned from experience sufficiently to arrive at some better adjustment of themselves to their environment than is now commonly effected. In the meanwhile, it is certainly legitimate to take advantage of all favourable currents of popular opinion, and, even at the expense of some curtailment of personal liberty, to protect classes who have displayed very little capability of protecting themselves. A measure forbidding the employment of young single women in bars where intoxicating drinks are sold, unless they had been actually so employed before its enactment, would at once give greatly increased security to barmaids now in possession and would close the door to many abuses of a manifestly flagrant character.

In a matter of this kind, as in relation to most other social questions, it might often be in the power of members of the medical profession very usefully to influence public opinion. It can be no matter for surprise if a silly girl, ignorant of the dangers she is incurring, likes to accept an employment of which she only knows that she will be expected to wear becoming dresses, to look her best, and to talk to people whom she would describe as "gentlemen." Her mother will know nothing of the probable effect of long hours of standing upon her health and will be likely enough to entertain and to encourage matrimonial hopes with regard to some of the "gentlemen" in question. The medical practitioner who has perhaps brought the girl into the world, and has seen her through the ailments of her childhood, if he has preserved the friendly and confidential relations with her family which it is always well to establish with patients, however humble they may be, might often be able to hold her back from a course only too likely to end in her destruction; and his advice, acting upon the class to which she belongs, might become a potent influence in reconciling them to the complete exclusion of their daughters from a form of occupation calculated to be detrimental alike to their physique and to their morality.

Annotations.

"No quid nimis."

MOTOR-CARS AND INCOME-TAX RETURNS.

A CORRESPONDENT raises the important question as to whether, in making a return for income-tax purposes, the cost of his motor-car, which he uses solely for professional purposes, should be charged to capital account with a depreciation each year or to profit and loss account—thus, in the latter case, treating the motor-car as a "trade

utensil." There can be no question of the advantage to the owner of the car in charging it up right away to profit and loss account and thus doing away with the necessity of calculating an adequate depreciation; but the local surveyor of taxes is not likely to agree to this course: he will insist on its being charged to capital account. With such a delicate piece of machinery as a motor car, the working life of which cannot be averaged at more than three years if used in daily practice, it is a serious matter to place its cost to capital account unless a substantial depreciation is claimed and allowed for it. At the end of three years a car originally costing, say, £300 will not fetch more than £70 or £80, showing an annual depreciation of something like 25 per cent. How many surveyors would agree to such a depreciation? The surveyor of the district in which our correspondent resides requires that his car should be charged to capital account and a 10 per cent. depreciation be charged for it—an obviously absurd amount considering its rapid depreciation. Of course, all the cost of upkeep, including chauffeur's wages, petrol, oil, recharging accumulators, repairs, renewals, insurance, garage charges, and so on, would legitimately be charged to profit and loss account, and on this point there is no difference of opinion; but it is certainly desirable that some general and equitable agreement should be arrived at between owners and surveyors on the particular point to which our correspondent alludes. In view of the importance of the subject we invited four of the leading associations dealing with income-tax to express their opinion upon the matter, and they kindly replied as follows:—

1. The motor car is certainly capital expenditure; your correspondent cannot charge it up in a lump sum against the expenditure of the year. He should have a depreciation upon it, and this depreciation can be charged up year by year, and eventually, when the car is worn out, he need charge up to capital only the excess paid for the new car over the value of the old car, as shown in his accounts, the rest being charged to profit and loss.

2. The actual cost of the motor-car should be charged to capital account.

3. The cost of the motor-car must be charged to capital account.

4. It would be to the disadvantage of your correspondent to charge the cost of a motor-car used entirely for professional purposes to capital account with, say, 10 per cent. depreciation and even considerably more. Our opinion of the correct way is to spread the cost over, at most, five years and charge besides repairs but not depreciation.

It will thus be noted that the first three opinions leave no room for doubt as to the course to be pursued. The last one would certainly seem to suggest that no hard-and-fast rule has as yet been laid down; but we doubt whether any surveyor will be found who will permit the course suggested to be carried out. The matter might with advantage be discussed and the exchange of opinions and experiences would undoubtedly prove useful.

WOOD AS HUMAN FOOD.

THERE is really no reason why, if the necessity arises, wood should not be employed as a source of food since it consists chiefly of cellular fibre which, on suitable chemical treatment, may be converted into sugar. But directly wood can have no value as a food for the human organism, as a correspondent in the *Times* has declared, inasmuch as the digestive juices are not able to deal with it. A certain amount of woody fibre is, we believe, digested by the horse by reason of the presence of a peculiar digestive enzyme in that particular animal's digestive canal which is capable of converting cellular tissue into sugar. The correspondent just referred to would appear to be in the possession of a similar peculiarity, for he writes the following (from a workhouse in Mile End Old Town): "Working in the firewood department I have discovered that common deal wood is a valuable food and medicine if cut small and eaten. Brown bread is not in it for its tonic and invigorating effect." The writer, of course, may mean this as a joke at the expense of the advocates of the brown loaf or of the administrative department of the workhouse. Chemistry,

at any rate, throws no light on either a "tonic" or an "invigorating effect" which could be fairly ascribed to the constituents of wood, for they consist almost entirely of fibre which is highly indigestible and which yields absolutely nothing of nutritious value to the action, powerful though it be, of the human gastric juices. As we have said, however, wood on long treatment with acid is eventually transformed into sugar which, of course, is a valuable food of its class. In the same way our worn-out shirts and collars could be converted into food, and possibly if this gentleman were to substitute a white shirt for his "common deal wood" the results would compare favourably with even white bread. His idiosyncrasy is, we believe, rare.

CHILDREN WHO ARE SPEECHLESS BUT HAVE HEARING.

MUCH care has of late years been bestowed upon the training of children defective mentally or otherwise. There is, however, a considerable class whose education is often neglected. We refer to children who have power of hearing—i.e., whose action can be controlled by spoken words, though they neither speak themselves nor make any response in words. A child may hear music and hum the tune or repeat it; he may go upstairs and find something when told to and yet remain speechless. These cases vary; usually examination shows no defect in the size and form of the head or development of the features but there is a lack of the normal brain spontaneity that can be coördinated in imitation of movements made by a teacher and such action as occurs is inexact, with a corresponding want of imitation of the movements produced in the face during articulation. The result is that speech remains absent from want of training of the necessary movements of the lips and tongue: the child will sometimes sing though he will not articulate. All that the children need is training in imitative faculty with daily practice in oral teaching, such as is almost universally used with deaf children. In public elementary schools there is often great difficulty in providing proper teaching for these speechless children who have hearing. The Elementary Education (Blind and Deaf Children) Act, 1893, is compulsory both upon the educational authorities and parents but the speechless children who have hearing do not come under its provisions and as the Education (Defective and Epileptic Children) Act, 1899, gives power to the authorities "to determine what children are defective," there is often a great difficulty in providing the special form of training needed by the children to whom we have referred. This suggests the desirability of amending and consolidating those Acts.

THE TEACHING OF HYGIENE AND PUBLIC HEALTH IN IRELAND.

THE provisions for the teaching of public health in Ireland are far from being what they should be. The greater portion of the work of a medical officer of health in Ireland is carried on by the dispensary medical officers who are apparently *ex-officio* medical officers of health of their respective dispensary districts. Most of these gentlemen are qualified in respect of their having obtained the diploma of the Conjoint Board of the Royal Colleges of Physicians and Surgeons in Ireland. These bodies apparently do not insist upon their students attending a course of lectures upon public health, for this important subject is combined with that of forensic medicine as one group in the third professional examination, and any student entering for this examination must send in a certificate of attendance for three months at lectures upon these two subjects. In these circumstances most of the course may be given up to forensic medicine, when all the attention that

public health will receive is a few lectures at the end of the course. The consequence is that many dispensary medical officers become *ex officio* medical officers of health without having had adequate training. On the other hand, the Royal University of Ireland requires its students to attend a course of 30 lectures in hygiene. Moreover, by a recently passed regulation, the students of Maynooth, who supply most, if not all, of the Roman Catholic secular clergy in Ireland, attend lectures in hygiene, and so, too, do the nurses belonging or affiliated to Queen Victoria's Jubilee Nursing Institute. Thus in a way the future medical officers of health may receive less instruction, so far as attending lectures goes, in the subject of hygiene than the parish priest or the district nurse who may work with them in their particular district. We are quite aware of the fact that public health and hygiene cannot be learned entirely by attendance at lectures on these subjects, but the fact remains that if lectures are given and if medical students have to attend them the teaching gives such students a sound foundation upon which to build further knowledge. The main facts of hygiene should be more appreciated than they are by the public, although we admit that in this direction popular attention is being aroused. A course of lectures upon sanitary matters has recently been given in the Royal College of Science, Dublin, the audiences being large. Such education of the people is all for good, for in many instances, although the medical officer of health may be energetic and well informed, his efforts for reform are entirely neutralised by the ignorance of the populace with whom, through their elected representatives, he has to deal.

PALUDISM IN ANNAM.

Dr. Vassal has written in an interesting manner on his researches into the etiology of malarial fever in French Indo-China. His paper, entitled "Une Mission à Lang-Bian," appears in *L'Europe Coloniale*. The first interesting point which he establishes is that paludism does not respect high altitudes. "The sanatorium of Cilao at Réunion," writes Dr. Vassal, "though built at 1215 metres above sea level and enjoying an exceptionally good climate, suffered from an invasion of the endemic marsh fever." Dr. Laveran's investigations in 1880 having established the fact that the malady is caused by the bite of anopheles, a species of mosquito which introduces hæmatozoa into the blood, Dr. Vassal confirms this fact by declaring that "alone among all mosquitoes the anophelines contract and propagate malarial infection. Where there are no anopheles," he says, "there is no paludism." A proper diagnosis, he maintains, can only be made by the microscope. But the natives of Annam show the greatest repugnance to yield up a single drop of their blood for examination—under the influence probably of some deep-seated superstition. As it happens sometimes, too, that the hæmatozoon is not to be met with in the peripheral circulation, the observer is constrained to direct his attention to the state of the spleen, as the protozoon causes congestion and inflammation of this organ as well as of the liver and bladder. Splenic hypertrophy in the case of children is so noteworthy a symptom that Koch has already called attention to the percentage of children thus affected as an easily established "endemic index" of the malady. In his quest after samples of Annamite children's blood Dr. Vassal seems to have been regarded as a regular "bogey-man" in the district. "For this reason," he writes, "the village of Kim-nom would not allow me to examine the children and the villages of Dang-kia and M'loné refused to be vaccinated," for I made a point of rendering what service I could to these forlorn people in the course of my researches. . . . Whenever I draw near the

Men women and children would shut themselves up in their houses. At last the master of the house would venture out, followed perhaps by a few young men, and while my instruments were in process of boiling my distributions of pearls and tobacco would begin to take effect. Little by little the doors of the huts would open and the children would be brought out by their mothers. Each child always received a certain number of pearls . . . and while I vaccinated I was on the look out for paludic symptoms. The research was pursued under cover of the vaccination and when I came across a sympathetic subject I would manage to get a drop of blood. . . . I found two types of malarial fever—the malignant tropical tertian and tertian fever in the strict sense. At the period of observation (July and August) the rains had commenced and the rice fields were flooded—without doubt a favourable period." The prevalence of the disease, as ascertained by Dr. Vassal, is astonishing, 84 per cent. of the natives being affected. At a place eight kilometres from Drau he examined 16 natives and found that all were affected. Here, he says, "the example of one family may be cited. The father had an enormous splenic tumour. One child was rickety, and seemed to have the 'abdomen of a batrachian,' so swollen out was it by his spleen. The mother was enceinte, and so menaced by the fever that the worst results were to be anticipated. Another wife had died with her child a few days after confinement, owing to an attack of fever." A last point of interest raised by Dr. Vassal is the question of clothing. "In the hygienic conditions," he writes, "in which the Annamites of Lang-bian live, relapse becomes inevitable, and cold is perhaps the cause which brings the fever back most easily. The Lang-bian Annamite has nothing to protect him from the cold. His clothing and his dwelling are the same as in the plain. His food becomes insufficient; he has no fresh fish. . . . Rice and salt fish cost ten times what they are worth. An Annamite can only live at Lang-bian by wearing warm clothes and changing his food and method of living, just as an Annamite dresses and lives like a European when he removes to the metropolis."

ARTERITIS IN CONNEXION WITH TYPHOID FEVER.

ARTERITIS is a well-recognised but rare complication of typhoid fever. In few of the recorded cases has a complete anatomical and bacteriological examination of the lesion been made. Hence the importance of the following case which was reported at the meeting of the Société Médicale des Hôpitaux de Paris on Dec. 1st, 1905, by M. E. Rist and M. L. Ribadeau-Dumas. A girl, aged seven years, was admitted into hospital on Feb. 24th, 1904, the eighth day of an attack of typhoid fever, in a state of great prostration. The temperature was 105.4° F. and the pulse was 90 and dicrotic. Vidal's reaction was obtained. On the 27th rose spots were observed. The case ran an ordinary course and the temperature fell by lysis, attaining 100° F. on March 9th. But after this deferescence was arrested and the temperature ranged from 100° to 100.4° until March 14th. On the 15th the temperature suddenly rose, reaching 104° in the morning and 105.8° in the evening, and the patient complained of severe pain in the right leg. Examination showed some pallor of the toes. The course of the femoral artery was tender and the pulsations of the popliteal artery were less distinct than on the other side. On the following days arterial pulsation was completely absent in the right thigh and leg. The limb was pale and the great toe was beginning to shrivel. On the 21st all the toes were mummified. On the 23rd a large bulla filled with sanguineous serum appeared on the upper third of the leg. Below this the skin was gray and softened. The toes were dry, violaceous, and of wooden hardness. Bullæ appeared on

the upper part of the leg, indicating the line of demarcation. The patient suffered from intolerable pain and amputation was performed on April 1st. It was necessary to amputate in the upper third of the thigh in consequence of the impermeability of the arteries. Recovery was uneventful. At the operation the femoral artery was obliterated at the point where it was divided. In the upper part, corresponding to the middle third of the thigh, the artery formed a hard rounded cord. Lower it became irregular and had a moniliform appearance. In the popliteal space the artery was enlarged and flattened and its contents were softened. These changes were also found in the tibial and peroneal arteries and in their branches. Two abscesses were found in the muscles—one of the size of a walnut in the adductor magnus and the other, of the size of a hazel nut, in the vastus internus. Around the abscesses the muscles had a greyish tinge. Microscopic examination showed only slight change in the upper part of the femoral artery. There were some collections of leucocytes in the adventitia and the endothelium was a little thickened. The vessel was occluded by a fibrinous clot. The popliteal artery was much more altered. It contained pure pus and its walls were in process of destruction. The internal coat had completely disappeared, the middle coat was infiltrated with polynuclear leucocytes, and the adventitia was replaced by a mass of leucocytes, traversed in places by fibres of connective tissue. At a higher level the changes in the artery were less intense and it contained fibrinous clot. Still higher there was only endarteritis. In the contents of the femoral artery and in the pus of the muscular abscesses the typhoid bacillus was found in pure culture. Thus the bacillus was the cause of the obliterative arteritis.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

THE lectures of the present year to be delivered before the Royal College of Physicians of London, Pall Mall East, S.W., are as follows.—The Milroy lectures will be given by Dr. W. H. Hamer on March 1st, 6th, and 8th, the subject being *Epidemic Disease in England—the Evidence of Variability and of Persistency of Type*; the Goulstonian lectures will be given by Dr. H. Batty Shaw on March 13th, 15th, and 20th, the subject being *Auto-intoxication*; the Lumleian lectures will be given by Dr. D. Ferrier on March 22nd, 27th, and 29th, the lectures being on *Tabes Dorsalis*; and the Oliver-Sharpey lectures will be given by Dr. E. I. Spriggs on April 3rd and 5th, the subject being the *Bearing of Metabolism Experiments upon the Treatment of Some Diseases*. The days of the week for the delivery of the lectures are Tuesdays and Thursdays and the hour of delivery is 5 p.m.

PARISH MEDICAL OFFICERS IN AUSTRIA.

THE Vienna correspondent of the *Standard*, in the issue of that journal of Jan. 20th, gives a grim account of the position of parish medical men in Austria. The total number of these officials in Lower Austria is, he says, 450. Of these, only 340 are able to keep themselves respectably. Only 170 can educate their children and 145 can only live by taking extra work themselves or by their wives doing the same thing. That is to say, the medical men act as wine merchants on commission or take some similar post and their wives do needlework or act as post-mistresses or managers of shops. More than half the medical men in question are compelled to send their children out to work. The average salary is about £25 per annum and although some get more yet others get less. The fee for vaccination is 2d., which includes the vaccination, filling up two certificates, and attendance for eight days. The correspondent continues: "For death certificates he does not get even the English shilling nor for

the notification of infectious diseases."....." There is, of course, no such thing in England as a fee for filling up a death certificate and the correspondent has evidently confused the shilling paid to the medical officer of a public institution for notifying a case of infectious disease. However, the Austrian medical men are going to strike and the communal authorities are said to have replied that if the medical men will no longer vaccinate there are plenty of quacks who will. This is a foolish argument, but no more foolish than kindred arguments put forth by antivaccinationists in this land. It is for the interests of a community to see that its medical men are paid a salary which will not only enable them to live but which will also enable them to devote their best energies to the task of guarding the health of their fellows against the inroads of disease.

WHAT IS DISTILLED WATER?

FOR the purposes of the Sale of Food and Drugs Act distilled water has been held to be a drug, and odd as this definition may appear to be it would after all be difficult to find any more suitable appellation. Distilled water is practically a chemists' commodity, may even form, and has formed, the sole item in a medical prescription, and it is 'an official preparation of, and is defined in, the British Pharmacopœia. This last fact implies its use as a drug in medicine. In the proceedings taken at Marylebone police court against a druggist, the defendant "was summoned for selling to the prejudice of the purchaser a drug—namely, a pint of distilled water—which was not of the nature, substance, or quality of the drug demanded." Sir Thomas Stevenson stated that he had analysed a sample of the water and had found it to be very dirty and full of mouldy growths and that it gave an appreciable deposit. The British Pharmacopœia requires distilled water to be colourless, tasteless, and odourless and when evaporated it should leave "at most a scarcely visible residue." Clearly the sample in question did not conform to these requirements and, legally speaking, any substance defined in the Pharmacopœia is a drug. The defence was that it was assumed that the water was required for photographic purposes but no question on this point was asked at the time the purchase was being made. The defence was hardly justifiable since it is essential in photographic processes to employ distilled water and it is hardly likely that photographers would incur the expense of procuring distilled water if ordinary tap water would answer the same purpose equally well. The defendant was fined 10s. with £3 3s. costs, the magistrate remarking that it was not suggested that he had done anything fraudulent or that reflected on his character.

THROMBOSIS OF THE RECEPTACULUM CHYLI AND CHYLOUS ASCITES IN CIRRHOSIS OF THE LIVER.

IN the *Medical News* (New York) of Nov. 11th, 1905, Dr. H. J. Nichols has reported a case of cirrhosis of the liver complicated with thrombosis of the receptaculum chyli and chylous ascites. Cases have been recorded of thrombosis of the thoracic duct near its junction with the subclavian and jugular veins but not of thrombosis at a lower level. The patient was a man, aged 74 years, addicted to alcohol. He was admitted to hospital on March 18th, 1905. The abdomen was distended and tympanitic and covered with a network of enlarged veins which extended to the lower part of the chest. In these the blood flowed from below upwards. At the bases of the lungs resonance was impaired and a few liquid râles were heard. The heart was slightly enlarged to the left and a mitral systolic murmur was heard. The legs

were œdematous. The liver dulness extended in the nipple line from the fourth to the seventh ribs. There was some dulness in the flanks. Incisions were made in the legs and saline purgatives and infusion of digitalis were given without relief. The legs became more distended and the abdomen more swollen, with marked dulness in the flanks, fluctuation, and dyspnoea. On March 28th paracentesis was performed and yielded 5700 cubic centimetres of fluid. The abdomen became lax and the œdema disappeared. The fluid re-accumulated. On April 6th 6200 cubic centimetres were removed and on the 16th 7800. On each occasion the fluid presented the same striking appearance. It was milky white, with a tinge of pink. On standing the pink colour disappeared and a red deposit formed. The fluid contained 1 per cent. of albumin and 1.3 per cent. of fat. Microscopic examination showed no large fat globules but a number of fine granules in constant motion. There were 24,000 erythrocytes and 1800 leucocytes per cubic centimetre. The latter consisted of small lymphocytes, 66.5 per cent.; large lymphocytes and transitionals, 13.5 per cent.; and polymorphonuclears, 20 per cent. The patient became comatose and died on April 26th. A necropsy was made. The abdomen contained about 2800 cubic centimetres of pink fluid similar to that removed during life. There was a typical hobnail liver which weighed 1400 grammes. The receptaculum chyli and thoracic duct were occluded by a firm, fibrous clot. The mitral valves were thickened and insufficient. Very few cases of chylous ascites associated with cirrhosis of the liver have been recorded. The nature of the connexion between these conditions is not clear.

POISONING BY OLEANDER.

IN THE LANCET of Dec. 30th, 1905, p. 1894, Dr. F. Lucas Benham referred to the poisonous nature of oleander and desired information as to what instances of poisoning by that shrub are known. In the event of no records of its toxic effect being forthcoming there is direct and corroborative evidence sufficient to suggest the symptoms to be expected in cases of poisoning by oleander. It has been shown by M. Dubigadoux and M. Durieu¹ that the branches of the Algerian oleander yield on incision a poisonous, milky juice, from which can be isolated a substance chemically and physiologically identical with strophanthin, the glucoside to which strophanthin owes its activity. The generic name of oleander is *Nerium* and it belongs, as does strophanthus, to the natural order Apocynaceæ or the periwinkle family. To the same order belongs the ouabalo tree, the wood of which yields the glucoside ouabain, resembling strophanthin in its chemical constitution and physiological action but being much more toxic. Apocynum or Canadian hemp, another member of this family, contains two active principles which act as cardiac tonics in a similar way to digitalis. Another member of the family, the white quebracho, is exceedingly active, affecting and, finally, paralysing the respiration, central nervous system, and heart. It is evident that the well-known members of the family to which oleander belongs have a powerful action on the heart. Digitalis itself, the best known of the cardiac tonics, is a member of a closely allied family, the scrophulariaceæ. It is probable, therefore, that oleander also exerts an action on the heart. It does not necessarily follow that the plant is equally active when grown in other countries—e.g., in South Australia. It is well known that drugs vary enormously in respect of their active principles and potency according to the climate and soil in which they grow. Digitalis affords a good example of this. It has been shown by M. François Franck² that from 0.2 to 1.0 gramme of the leaves

collected in one part of France, the Vosges, produces a marked physiological effect, whereas in other parts as much as from four to eight grammes are given, while in Roumania so large a dose as from 12 to 15 grammes of the powdered leaves has been given without producing toxic effects. According to Allen³ the leaves of oleander contain two glucosides, oleandrin and nerin, having physiological effects closely analogous to those exhibited by digitalis. Oleandrin is alleged to have basic properties, though it is free from nitrogen, while nerin is not improbably identical with digitalein.

A REDUCTIO AD ABSURDUM OF THE PHARMACY ACT.

THE announcement was recently made in the *Financial Times* that a company had been registered to acquire a druggist's business at Newmarket with a unique directorate. Of the seven gentlemen holding the position of director five are professionally connected with horse-racing; they are A. D. Sadler, S. Loates, and G. Chaloner, trainers of race-horses; G. H. Martin, jockey; and E. Moore, turf commission agent; the remaining two directors being an auctioneer and a butcher. It is noteworthy that the board of directors is singularly lacking in members possessed of even a nodding acquaintance with pharmacy and the allied sciences. The situation of these gentlemen is decidedly Gilbertian. Are we to think that they have been chosen with a view of bringing their special knowledge to bear on any branch, however remote it might be, of the art of pharmacy. The *Financial Times* ironically suggests that this may be an application of the joint-stock principle to the medical treatment of horses and that the butcher and auctioneer may come in useful after the other "druggists" have had their innings. It emphasises an anomaly in the Pharmacy Act of 1868, whereby it is possible for limited companies of unqualified persons to practise as druggists and to use the title of druggist. The only safeguard to the public consists in the fact that the assistants employed in the shops of such companies must possess a pharmaceutical qualification in order to sell or to dispense scheduled poisons.

THE STRAITS SETTLEMENTS POISON ORDINANCE, 1905.

COLONIAL legislators frequently have the advantage over those who make laws for the mother country in that they do not always have to consider old-established customs or vested interests. In the *Pharmaceutical Journal* of Jan. 6th are given to the new rules made by the Governor in Council under Section 13 of the Straits Settlements Poison Ordinance, 1905, which afford a case in point. They include several wise restrictions which are not imperative in this country. The new Ordinance contains Schedule A, Parts I. and II., almost similar to Schedule A of the Pharmacy Act, 1868, and the same precautions have to be observed in the retail sale of poisons in both parts of the schedule as obtain in this country. It is noteworthy that sulphonal is included in Part I. In addition the rules provide that no poison shall be sold to any person under 18 years of age. Licences to sell by retail the several poisons named and described in Schedule A shall be issued only to such persons as are duly registered as licensed chemists and druggists under the Morphine Ordinance (XIV. of 1905). Schedule B is a new and commendable feature of the Ordinance. It includes several poisons which can only be sold wholesale by such persons as may be granted a wholesale licence under the provisions of the Ordinance. The quantities shown opposite each poison in Schedule B shall be deemed the minimum amount constituting a wholesale transaction.

¹ Journal de Pharmacie et de Chimie, 1893, p. 433.
² Archives de Physiologie, 1891 and 1892.

³ Commercial Organic Analysis, vol. iii., part 3, p. 137.

Records of the sale of such poisons must be kept in the form prescribed by the rules. It shall be lawful for any police officer not below the rank of inspector, and for the licensing officer under the Ordinance in each settlement, and for any officer of the medical department authorised in writing by the licensing officer, at all reasonable times to inspect the books kept under these rules and to take copies and extracts therefrom. The poisons under Schedule B, with the quantities named, are: arsenic and all preparations of arsenic, 5 lb.; mercury and all its preparations, except cinnabar, 1 lb.; lead acetate, 1 lb.; antimony and all its preparations except the sulphide, 1 lb.; carbolic acid, 5 gallons; phosphorus, 1 lb.; cyanide of potassium and all other metallic cyanides, 5 lb.; oxalic acid and all other oxalates, 5 lb.; and patent medicines containing any of the poisons enumerated in Schedule A, Parts I. and II., except those containing opium or morphine, as defined in Ordinance IX. of 1904 and Ordinance XIV. of 1904 respectively, 1 original packet. In addition it is provided that the following poisonous chemicals used in photography, if sold in original packets of one ounce or over, will be deemed wholesale within the meaning of this Ordinance: ferrocyanide of potassium, iodide of mercury, perchloride of mercury, oxalate of ammonium and potassium, sulphocyanide of ammonium, ferrocyanide of copper, and lead acetate.

WHAT IS WHISKY?

A FURTHER stage was reached in the whisky case at the North London police court last Monday, when the principal witness was Professor Sir James Dewar. Questioned as to his view of the meaning of the word whisky Sir James Dewar, speaking as a chemist, said it was a generic name given to several varieties of ardent spirit prepared in Ireland and Scotland from a distillation of a fermented infusion of grain technically called "wash." Whether the distillation was conducted in a patent or a pot still did not affect, in his opinion, this definition; both stills could be made to produce similar results. The pot-still whisky was the dearer of the two because it could not be produced so economically as the patent still, in which the process was more expeditiously done. He did not agree with the statement in the certificate of the borough analyst that whisky should contain 380 parts of secondary products per 100,000 parts of absolute alcohol present. The average, he thought, would be 240, though 100 would be very low and could scarcely be called whisky. In answer to a question put by the magistrate Sir James Dewar said that if pot-still whisky were sent to London and mixed with patent-still spirit it would not be Scotch whisky. Mr. Tatlock, the public analyst for Glasgow, re-called, said that pot-still whisky was unwholesome until matured by age, whilst patent-still spirit was "beautifully light," which drew from the magistrate the suggestion that there would be no harm in stating upon the bottle the words that "this whisky was composed one-third of nasty pot-still spirit and two-thirds of beautiful patent-still spirit." The witness was understood to assent to this but with the adjectives "nasty" and "beautiful" deleted. The hearing was again adjourned.

HERNIA OF MECKEL'S DIVERTICULUM.

It is rare to find the vermiform appendix in a hernial sac and yet the appendix is normally present in the body and is placed close to both the internal abdominal ring and the crural ring. It is still more rare to find Meckel's diverticulum in the sac of a hernia and this is what we should expect, for the diverticulum occurs in only about 2 per cent. of all bodies examined and therefore the probability of its appearance in a hernia is 50 times less than is the case with a vermiform appendix, even without taking into account the fact that the diverticulum is as a rule not very near to the usual sites of hernial protrusions. This form of hernia was

first described by Littre more than 200 years ago, in 1700, and has been called Littre's hernia, but much confusion has been caused by partial enterocele having also been named Littre's hernia; and, indeed, there is reason for thinking that Littre was the first to describe this condition also, though from the clearer description of a partial enterocele which was given by Richter in 1779 Richter's name is deservedly applied to the latter. In spite of its great rarity cases of Littre's hernia or hernia of Meckel's diverticulum have been recorded from time to time. Even when only the diverticulum is included in the sac and strangulation occurs, all the ordinary symptoms of strangulated hernia may be present and yet there is no actual obstruction to the onflow of the intestinal contents. Until recently this form of hernia was only seen in cases of strangulation. In the present issue of THE LANCET we publish an account of a case of Littre's hernia, recorded by Mr. C. B. Howse, and in this the variety of hernia was recognised during the operation for radical cure. Now that the operations on non-strangulated herniæ are common we may expect to find more cases of Littre's hernia.

THE medical officer of health of the Cape Colony states that for the week ending Dec. 22rd, 1905, the condition of the colony as regards plague was as follows. No case of plague in man or in other animal was discovered throughout the colony except at Port Elizabeth, where out of 307 rodents bacteriologically examined two mice proved to be infected by plague. As regards the Mauritius a telegram from the Governor received at the Colonial Office on Jan. 18th states that for the week ending Jan. 18th there was 1 case of plague and 1 death from the disease.

THE committee of the Fifteenth International Congress of Medicine to be held at Lisbon has decided to postpone the date by which all scientific communications must be sent in until March 15th. The papers, together with a résumé of their contents in French, English, or German, should be addressed to the general secretary of the Congress, Professor Miguel Bombarda, New School of Medicine, Lisbon.

A SERIES of 12 lectures will be delivered by Dr. Francis Warner under the auspices of the National Association for the Feeble-Minded at Denison House, Vauxhall Bridge-road, London, S.W., beginning on Monday, Jan. 29th, at 6 P.M. The lectures are in connexion with the extension lectures of the University of London.

THE annual general meeting of the Neurological Society of the United Kingdom will be held at 11, Chandos-street, Cavendish-square, London, W., on Thursday next, Feb. 1st, at 8.30 P.M. Mr. W. Bateson, F.R.S., will read a paper on Mendelian Heredity and its Application to Man.

A WORKING COLONY FOR FEEBLE-MINDED CHILDREN.—At a meeting of the Metropolitan Asylums Board on Jan. 20th a letter was read from the Local Government Board assenting to the proposals of the managers (1) to use the Bridge School, Witham, Essex, as a working colony for male feeble-minded cases, when that institution is no longer required for ringworm cases; and (2) to the transfer on medical advice of children from the London homes for feeble-minded to the working colony before such children attain the age of 16 years on the understanding that no such transfers will be made until such additional accommodation for feeble-minded cases has been provided. The Board stated that it assented to the second proposal provided that only cases were sent which are either unlikely to improve any more in subjects taught at the special schools of the London County Council or to improve so little as to make their retention in the ordinary homes no longer advantageous, and further, that suitable classification of the children removed according to sex and age and apart from adults was carefully attended to.

THE NOSE IN LITERATURE.

BY P. TETENS HALD, M.D.,

ASSISTANT SURGEON TO THE EAR, NOSE, AND THROAT CLINIC
KOMMUNE HOSPITAL, COPENHAGEN.

It is partly in order to draw attention to the writings of an English colleague, dead these many years, that I venture to lay the following lines before the medical public. By chance I picked up some time ago a book, now, as I suppose, only little known, the "Illustrations of Sterne," by John Ferriar, M.D. He evidently was, as so many of the profession have been, a hunter of curiosities and as I have worked a little in the nose and throat line his collection of quaint quotations concerning the nose appealed very much to me. Once my interest being stirred I made further researches in the same direction, some of which are reproduced in the following lines. I hope the reader will not find them too tedious.

Perhaps there has never existed a man who has written of the nose in more laudatory terms than the Bologna surgeon Tagliacozzi. In his "Chirurgia nova," where he describes the Italian rhinoplastic operation, is to be found a very entertaining chapter with the heading, "De narium dignitate," in which he expresses himself in the following manner: "Nares igitur, ut earum dignitatem consideremus, quantum pulchritudini splendoris afferant, id satis explicari non potest. Quanvis enim cuique faciei partium suus honor, sua gratia adeit, quae suavi rythmo disposita, in augustissimam formae speciem conspiciunt, peculiaris tamen nasi ratio est, ut concinnus si fuerit, summopere faciem commendat; distortus vero, aut pravus aut simus aut vulnere notatus totam formae honestatem evertat." And in another place: "Inest praeterea naso nescio quid angustum et regium; an quia forma corporis et animae decoris index sit: an quia peculiaris quaedam imperandi dexteritas et prudentia in eo eniteat."

In order to show how essential the nose is in making a figure beautiful or ugly Tagliacozzi brings forth the two following historical incidents. In the first a somewhat uncoquy part is played by a Byzantine courtier, "qui ab ipse ab Roberto filio Petri Antisiodoriensis nares sponsae praecidit, ut qua causa allectus fuerat Robertus ad sponsam raptam, eadem spoliatus graves aculos doloris persentisceret." This really appears to have occurred, though the quaint stating of the motive must be answered for by Tagliacozzi himself alone.¹ About the historical truth of the next narrative, however, I feel happy to be able to entertain some doubt, as otherwise it would form a rather heavy item on the bill run up in former times in England by some of my ancestors. "Sic sancta Eba, regii sanguinis Angla, Colymbaniensis monasterii praeses, ut funestam irruentium Danorum libidinem a corpore suo averteret, una cum ceteris religiosae illius vitae comitibus nares sibi obtruncavit, quo vulnere, non tam indecoro quam honesto, castitatem Deo promissam casta foemina redemit."² Modern historians at least³ refuse to believe in this. Whether the French nuns, who according to Hovorka⁴ on a similar occasion also cut off their noses, really have done so I do not know, having been unable to find his authority. If they have done it they probably have brought about what they wished for, for, as Tagliacozzi says: "Narium apice abscisso panduntur sinus et partium internarum recessus, vasti patent hiatus et cavernae, instar antri Tryphonii⁵ obscurae; horrendum certe et abominandum aspicientibus spectaculum."

As an additional reason why the nose should be honoured Tagliacozzi mentions that it forms a sign of recognition and proves this by a quotation from Virgil. He might as proof have chosen the following story from a remarkable book then very much in vogue—viz., Henri Estienne's "Apologie pour Hérodote."⁶ Dramatis personae

are: "Un seigneur de Bourges nommé Boyuier," and several witnesses bribed to give evidence against him in a case of murder; these latter, however did not remember their lesson correctly: "Car au lieu que pour une des meilleures marques pour reconnoistre ledict Boyuier, on leur avoit dict qu'il avoit un nez fait à manche de rasoir, interroguez séparément par le président à quoy ils le reconnoistroyent, respondirent tous d'un mesme accord qu'ils le pourroyent reconnoistre aisément à un coup de rasoir qu'il avoit en sur le nez. Tellement que leur estant confronté ledict Boyuier contre lequel ils entendoyent déposer, dirent que ce n'estoit pas cestuy-la, pource qu'il n'avoit point de cicatrice sur le nez et ainsi estans decouverts, furent pendus: et le suborneur et faux accusateur fut decapité, et mis en quatre quartiers: mais en effigie: qui fut un grand avantage pour sa personne."

How far back the prepossession against misshapen noses dates is demonstrated by the Levitical law that excludes from the office of priest those endowed "vel parvo, vel grandi, et torto lequele ils entendoyent déposer, dirent que ce n'estoit pas cestuy-la, pource qu'il n'avoit point de cicatrice sur le nez et ainsi estans decouverts, furent pendus: et le suborneur et faux accusateur fut decapité, et mis en quatre quartiers: mais en effigie: qui fut un grand avantage pour sa personne."

As it is well known, the Romans have given name to a certain form of aquiline noses. Nevertheless, one finds that they did not think crooked noses beautiful. So Clitipho mentions the bride offered him by his mother in the following uncomplimentary terms:⁷

"Rufarum illam virginem
Ciclam, sparso ore, adunco naso? Non possum, pater."

Nor did they like long noses; see, for instance, the catalogue of a Roman matron's attractions and defects⁸:

"O crurs, O brachia! Verum
Depygis, nasuta, brevi latere ac pede longo est."

Generally speaking, the nose played a very great, and to us sometimes strange, part in the language of the Romans of antiquity. It is, for instance, intended as a great praise when Horace says about the poet Lucilius that he was possessed of a well-blown nose⁹:

"Facetus,
Eunuchus naris, durus componere versus."

The word long-nosed (nasutus), nay, nasus itself, stands for acumen and criticism. Perhaps this may be accounted for as notions produced by a popular doctrine of physiognomics. This science has from antiquity down even to our days had its fervent votaries, but presumably none more persuaded than Lavater. It is nearly incredible what he is able to read out of a physiognomy. So by the discussion of Benjamin West's profile he expresses himself literally as follows:¹⁰ "Bis zum Nasenloche geht der reinste Ausdruck von Geist—Er sinkt schon, erlösch schon ein wenig unter der Nase; nicht dass der Umriss unedel werde; aber er sinkt von Größe gegen Mittelmässigkeit herab." His enthusiasm induces him in another place,¹¹ where he has given a description of the nose *comme il faut*, to declare: "So eine Nase—ist mehr werth als ein Königreich." I wonder only how he would have valued a nose like that of Pamphagus¹² that might be used as an extinguisher, a pair of bellows,

boarding-pike, a trumpet, a pick-axe, a scythe, an anchor, a fork, or a fishing-hook.

But it was not only Lavater's eyes that possessed such singular discerning powers, also his nose appears to have been unique.¹⁸ "Ich glaube, dass ein feiner Geruch die Nationen riechen—und vielleicht eher unterscheiden könnte, als das Gesicht. (Mein Geruch) ist fein genug, das Daseyn oder Nache-syn gewisser Krankheiten zu bemerken, und wenn ich in gewisse leere Zimmer eintrete, so kann ich manchmal mit Zuversicht sagen: 'Hier muss ein Hektikus oder Maniakus, oder einer, der im Begriff ist es zu werden, gewesen seyn.' Und zwar waren meistens solche da gewesen, an deren Gesichte sich die Krankheit noch nicht zeigte. So kam mir einmal ein gewisser Geruch mit dem Besuch eines Fremden in mein Zimmer, den ich natürlicher Weise für ganz individuell hielt und weiter nicht achtete. Mehr als ein halb Jahr lang hernach kam mir derselbe Geruch, von dem ich ein halb Jahr lang keine Spur mehr hatte, so wie ich vorher keine davon gehabt hatte, wieder mit einem Fremden in mein Zimmer. Bald vernahm ich, dass dieser aus derselben Gegend kam. Ich musste also sogleich auf den Gedanken fallen, dass es Nationalgerüche geben könnte."

One scarcely knows whether the author wishes assertions of this kind to be taken seriously or not. This doubt does not exist when we direct our attention to the following jocos theories as to the etiology of certain malformations of the nose. One of these theories is quoted by Ferriar¹⁹ out of Bouchet's "Serées": "Ceste chaleur fait aussi, adjousta il encores, que les Mores sont fort camus, et diriez qu'on leur a coupé le nez sur le billot. cela procédant de la grande chaleur, qui ne permet pas que les os et les cartilages croissent beaucoup, comme venant d'une matière inutile et vacante: les petits enfans le confirment bien, lesquels estans chauds sont camus, ayans en leur jeunesse le nez fort court."

Another very widely spread theory is the ore first, as far as I know, mentioned by Rabelais²⁰: "Pourquoy, dist Gargantua, est ce que Frère Jean a si beau nez? Trut avant, dist le Moine. Selon vraye philosophie monastique c'est parce qu'il ma nourrice avoit les tetins moletz; en la lactant mon nez y enfondroit comme en beurre, et là s'eslevoit et croissoit comme la paste dedans la met. Les durs tetins de nourrices font les enfans camuz." This idea Sterne has eagerly taken up and developed.²¹ "Now Ambrose Paræus convinced my father that the length and the goodness of the nose was owing simply to the softness and flaccidity in the nurse's breast, as the flatness and shortness of *prune* noses was to the firmness and elastic repulsion of the same organ of nutrition in the hale and lively, which though happy for the woman, was the undoing of the child, inasmuch as his nose was so snubbed, so rebuf'd, so rebated, and so refrigerated thereby, as never to arrive *ad mensuram suam legitimam*; but that in case of the flaccidity and softness of the nurse's or mother's breast, by sinking into it, as into as much butter, the nose was comforted, nourished, plumped up, refreshed, refocillated, and set a-growing for ever." Sterne here quotes Ambrose Paré as his authority. Remembering the coolness with which Sterne has ascribed a grand folio, "De Nasia," to a never before or since heard of author, the great and learned Hafen Slawkembergus, one might feel tempted to think that also his assertion about Ambrose Paré was a hoax. But the great French surgeon really has written something of a similar kind and, as is clearly to be seen, in full earnest. In the chapter Des Mammelles et de la Poitrine de la Nourrice he says: "Elle doit avoir la poitrine large et les mammelles assez grosses, et non laches et pendantes, moyennes entre dures et molles. D'abondant l'enfant imprime le beut de son nez à la mammelle: la trouvant trop dure se farsche, et ne veut léter, et quelquefois en devient camus."

In order not to become too tedious I am going to stop here. The most appropriate way of finishing I can think of is by quoting the well known lines:²²

"Nasutus als trughe lieet, s a denique nazus
Quantum roborat ferre rotatus Atlas,
Et possit ipsum in decidere latium.
Nou petes in nazus dicere plura meas,
Ipse ego quam dixi."

THE DECLINING BIRTH-RATE AND FERTILITY OF MARRIAGE IN ENGLAND.

Two able papers on this important subject were read before the Royal Statistical Society on Dec. 19th, 1905; one jointly by Dr. Arthur Newsholme, medical officer of health of Brighton, and Dr. T. H. C. Stevenson, assistant medical officer to the Education Committee of the London County Council; and the other by Mr. G. Udny Yule, Newmarch Lecturer in Statistics, University College, London. The discussion on these papers was postponed and continued after the delivery of the President's address at the subsequent meeting of the society on Jan. 16th. Both these papers naturally treated the subject mainly from a statistical standpoint, with a view to analyse and if possible to explain the extent and true purport of recent changes in English marriage-rates and birth-rates. A careful study of these papers enforces two important and useful conclusions. In the first place that the crude birth-rate—that is, the proportion of registered births to population, unless duly corrected for the age-distribution of the population, very considerably understates the recent marked decline of the true birth-rate. The recent decline in the birth-rate has indeed caused a marked change in the age-constitution of the English population. The important bearing of varying age-distribution in different populations on marriage-rates, birth-rates, and death-rates has been urged by successive statistical superintendents at the General Register Office, and it is satisfactory to find that this fact is now very generally recognised by students of vital statistics. The second unavoidable conclusion to be deduced from these papers is that the recent steady decline of under-age marriages, and the somewhat general increase of age at marriage, causing a decreased proportion of young married women in the English population, accounts but for a very small part of the decline in the birth-rate.

Both papers, moreover, abundantly prove the existence of a marked and increasing decline in the birth-rate and in the fertility of marriage, that is in the proportion of births to a marriage. Dr. Newsholme's paper shows that the corrected birth-rate in England and Wales, which was 35.4 per 1000 in 1871, declined successively to 34.7 in 1881, 32.6 in 1891, and 28.4 in 1901, implying a startling increase in the rate of decline of fertility. With regard to what Dr. Newsholme and Dr. Stevenson style "social *felo-de-se*" it seems to be next to impossible to avoid the conclusion at which their investigation has led them. At the same time, however, it is well not to shut one's eyes to the fact that mathematical and statistical methods, even when handled as ably as they are in the two papers under consideration, are scarcely fitted to solve the problem of the true cause of this decreased and declining fertility of marriage in England.

There are many pessimists at the present time who, in the face of much cogent evidence to the contrary, persistently assert that the British nation is suffering from progressive physical deterioration. This assertion may, however, be true and if so it may quite possibly be the fact that this decline of fertility is, at any rate in part, one of the results of this physical deterioration. Careful study of these two papers and of the remarkable New South Wales report on the similar decline of fertility in that colony would, however, more probably lead to the conclusion that the true cause of this decline of fertility, here and elsewhere, is a serious decrease of moral stamina rather than the alleged increase of physical degeneration.

Mr. Yule's theory that economic factors are the main causes of fluctuations in marriage-rates and birth rates is more interesting than convincing. He states that having mathematically examined several individual factors in succession he finds that the movement of prices "is the only one that fulfils certain conditions which must hold good for the predominant cause of the changes in the marriage rate (if there be any single predominant cause) and that it does fulfil them fairly closely." As regards the marriage rate, Mr. Yule's figures appear to show that it rises with an increase in prices and also declines when they fall. That high prices should promote marriage seems paradoxical but high prices probably imply high wages and full employment and Mr. Yule's tables certainly support his theory.

²² Les Œuvres d'Ambroise Paré, Lyon, 1623, p. 725.

²³ Martial, Epigramm, xlii, 2, 1-5.

It is difficult, however, to agree with this statistician when he further asserts "that the course of prices has been in some way, directly or indirectly, an important cause in the changes that have taken place in the reproductivity of the race." It is beyond all doubt that this country, speaking generally, and including all classes, now enjoys a far higher standard of material prosperity and comfort than it did 25 years ago before this decline in the birth-rate set in. This seems to forbid us to attribute correctly this decline in the fertility of our race, except most indirectly, to economic causes.

There is an important branch of this subject which, so far as is possible, is fully and carefully treated in both the papers under notice—the inquiry whether this decline in the fertility of marriage is equally or unequally shared in the various social grades. It is not necessary to press the importance of this question to the future of our race which has been so well urged and fully discussed by Professor Karl Pearson. Unfortunately, the construction of trustworthy class vital statistics is at present fraught with almost insurmountable difficulty. The authors of both papers have endeavoured to estimate the relative decline of the birth-rate in different classes of our population by comparing the statistics of different metropolitan boroughs in which the varying proportion of domestic servants indicates a greater or less degree of material prosperity. Dr. Newsholme and Dr. Stevenson show in their paper that the London corrected birth-rate in 1903 ranged from 31·6 per 1000 in a group of boroughs in which the domestic servants did not average more than ten in 100 families, to 20·5 per 1000 in the group of well-to-do boroughs in which the domestic servants averaged above 66 in 100 families. It may be noted, however, that in the four other groups, comprising 65 per cent. of the entire population, the corrected birth-rate only ranged from 25·4 to 25·8 per 1000. It should also be pointed out that the group in which the high birth-rate occurred included several districts in East London containing a large proportion of alien Jews and that the high birth-rate therein has probably a racial rather than a true class signification. Unfortunately the authors of this paper have not found it possible, or at any rate have not attempted, to give any figures for these groups of London districts at a previous date and thus to throw light on the question whether the recent decline in the birth-rate has been greater in the well-to-do than in the poorer districts. In view of the unquestionable importance of this branch of the inquiry it may be hoped that the General Register Office will find means to furnish material for a closer and more satisfactory study of class birth-rates than is at present possible.

It seems desirable, in conclusion, to refer briefly to a fact that is clearly brought out in these two papers—namely, that the decline in the birth-rate is not due to the steady increase of the urbanisation of our population and that in point of fact the decline between 1881 and 1903 was actually greater in the selected rural counties than in the selected urban counties. It is stated that the decline in the urban birth-rate during these 12 years was only 15 per cent., while it was 18 per cent. in the selected rural counties. The fact, however, remains that the corrected birth-rate is still distinctly higher in our rural than in our urban populations, although there is no obvious natural explanation of this lower birth-rate in towns.

MEDICINE AND THE LAW.

The Smell of Fried Fish as a Nuisance.

A RECENT motion before Mr. Justice Kekewich in the Chancery Division for an injunction against persons carrying on a fried-fish business in Dean-street, Soho, ended in an admission that a nuisance was caused and an undertaking that it should be abated, subject to an agreement by the plaintiff not to enforce the injunction granted to him for a fortnight. The defendant, Sbanpitzki by name, carried on his trade on the ground floor and the plaintiff, Abraham, who conducted a business, said to have been established for over a century, in embroidering uniforms, complained that the penetrating and offensive smell of the fish fried in grease not only made his workpeople ill but impregnated the clothes which they wore and those upon which they worked so that the wearers of them, including his customers, were strongly objected. Difficulty had apparently been found in tracing the course of the odour and in ascertaining why it

reached the workshop upstairs so readily. The question had, however, been solved the day before the case came into court, when it was found by a surveyor that there were two chases or channels passing down the interior wall from the upper part of the house to the basement where the fish was fried, one of which contained a rainwater pipe and the other a soil pipe. The precise condition and destination of these pipes are not mentioned in the report we have seen of the hearing before Mr. Justice Kekewich, but considering the not very desirable course which they appear to take it is to be hoped that the soundness of the soil pipe itself came under the observation of the surveyor.

Robbing Out-patients at Hospitals: Singular Story.

A new and curious form of thieving has earned six months' hard labour for a woman who, if she had not carried on her evil practices quite so assiduously, might apparently have escaped detection for some time. Her method appears to have been to borrow a neighbour's baby and to take it to the out-patient department of a hospital as if for treatment. When leaving the hospital she simply placed the bogus patient in the perambulator or mail-cart in which some other little patient had been brought and departed. In this way she had succeeded in stealing at least 20 of these vehicles which she afterwards pawned, the institutions which she patronised being the West London Hospital and the Children's Hospital, Paddington-green. She appears to have confessed the regularity and persistence of her thefts, no other court being open to her as nearly 20 stolen perambulators and mail-carts were recovered by the police. The thefts were certainly ingenious.

A Sham Medical Practitioner.

Mr. McConnell, K.C., has passed a sentence of 12 months' imprisonment upon a man described in the calendar under the name of Forbes, a clerk, who had committed wholesale frauds under the titles of Baron Forbes and Dr. Forbes. The evidence of Detective-sergeant Bex with regard to the personation of a medical man by the prisoner is to be noted by any who may desire to employ alleged medical men of whom they know nothing without verifying their supposed qualifications. The detective stated that the prisoner had been a student at the Middlesex Hospital in 1879 but had not qualified. He had been to the Gold Coast, where a medical man of the name of Forbes was practising at the time whom he had probably met there. In 1893 he returned to England and since then had personated the gentleman mentioned, increasing the age which he assigned to himself for this purpose. He had been employed at various times by a firm of wholesale druggists and by several medical men of the strength of his pretended qualifications. Mr. McConnell in passing sentence, described this conduct of the prisoner as one of the worst features of the case and the jury expressed their approval of this view.

A Garbage-monger Fined £50.

At the Guildhall police court recently a fine of £50 with 5s. costs was inflicted by Alderman Sir Joseph Renal upon a butcher at Llanely. The defendant had bought for 8s. a pig which, considering the size of its frame, should have weighed at least 400 pounds. As a matter of fact, it weighed 249 pounds and the price given was equivalent to about 3d. per stone. Dr. W. Collingridge described the carcass as much wasted by tuberculosis and said that in every part its condition was disgusting. Sir Joseph Renals decided to treat the case, though "as wicked a one as he had ever had before him," as one of gross carelessness, and the butcher escaped prison. The frequency with which these cases are noted in our columns speaks not only for the vigilance of Dr. Collingridge, the medical officer to the corporation, but proves that in the matter of public health many purveyors of provisions to London are criminally ignorant.

HYGIENE OF COTTAGES IN AN AGRICULTURAL DISTRICT.

THE fact is too well known to need further emphasis that in many respects the large towns in England possess hygienic advantages which are absent in rural neighbourhoods. The domestic environment of the very poor in great cities too often abounds with serious faults and dangers, while the town workman, on the other hand, obtains systematic water-supply and drainage and a more rigid supervision

of the sanitary conditions under which he lives. The pure air of the country and the undefiled spring, which should mean so much in the preservation of health, too often count for nothing because the country labourer does not live in a manner to benefit by them. His home defiles them both. This is a general statement and many instances, increasing we hope and believe in number daily, could be adduced where the home of the agricultural labourer is most carefully planned and maintained, but in purely agricultural parts of England the labourer's cottage is too often lacking in proper accommodation and is in a deplorable sanitary condition.

We are led to these reflections—similar, we are aware, to many that have appeared in our columns—by a letter from a frequent correspondent which we may here quote. "Having been on a visit recently," he writes, "to a purely agricultural district in the Eastern counties, I availed myself of the opportunity to inspect, in a superficial manner, of course, certain labourers' cottages which attracted my attention. I made no sanitary inspection and had no *locus standi* from which to do so. I merely used my eyes and nose and I learned sufficient to warrant an expression of opinion the reverse of respectful to rural England. I may mention that I was brought up in the district but it happened that I had not visited it for about ten years. I found that on the whole the cottages were in a better sanitary state than when I was last in the neighbourhood, but there was such ample room for improvement that I could not feel cheered by the progress made. A typical labourer's cottage of the worse kind in that part of England is usually built of clay lumps; if bricks are used they are always of an inferior kind. The cottage contains, as a rule, two living rooms and two bedrooms, though sometimes the separate accommodation is less. The rooms are low and the windows are small and seldom opened, the floors of the living rooms are of brick, generally damp, and in a bad state of repair. The sleeping rooms are ill-lighted and ill-ventilated owing to the smallness of the windows and the lowness of the ceiling, and the roof is too often in a defective state, freely admitting rain and wind. If the cottage is structurally in a fairly good condition, and the household is small, no complaints are likely to be made; but if there are many children, as they grow up, overcrowding will lead to general impairment of the health of the family and it will be hardly possible to provide such separate accommodation for the boys and girls as decorum would suggest. Rheumatism is a disease to which the agricultural labourer is peculiarly liable. His predisposition to it may be accounted for principally by the exposure to vicissitudes of weather which is inseparable from his daily work and partly to the depressing influence of the draughty, damp, overcrowded cottage to which he returns in the evening. If he were better housed he might then obtain at home such rest and comfort as would counteract the fatigues of the day, but at present he can hardly count upon this. Overcrowding, again, not only predisposes to pulmonary tuberculosis among all the occupants of the cottage, but among the younger ones it creates a special liability to the spread of whooping-cough, scarlet fever, measles, and certain parasitic skin affections. It might be thought that a cottage in the country, even if it presented structural defects, would at least have the advantage of healthful surroundings, but the facts are only too often incompatible with this ideal. In almost all the cottages which I visited open wells are the chief sources of domestic water-supply. Many of such wells present every possible drawback from a sanitary point of view, being not only surface wells but placed in close proximity to the privy and the pig-sty. If the well is in the garden the result is practically the same, for the privy and the pig-sty are the source of the manure with which the garden is fertilised."

A well-known American medical man, Dr. William C. Daggett of New Haven, read before the Connecticut Medical Society in the spring of 1904 a paper in which he insisted that the source of urban typhoid fever must be sought in the country, and that to abolish the disease the work of sanitation should be initiated in the rural districts. He contended that visitors to the country brought back typhoid fever to the towns and that the disease was also conveyed by the agency of milk and vegetables. In his opinion the starting-points of epidemics of typhoid fever occurring either in their immediate neighbourhood, or more probably in some distant town the water-supply of which has been infected

by the privy. Of course, the conditions of the agricultural districts of Great Britain and of the United States are by no means alike and possibly Dr. Daggett's view of the situation may be too gloomy, but the water-supply of many country cottages is seldom, if ever, sufficiently protected against the risk of contamination. Mr. Rider Haggard has pointed out in forcible terms that one of the reasons which induce the rural population to migrate to the towns is the difficulty of obtaining proper house accommodation on reasonable terms in country districts. The question, therefore, of providing agricultural labourers with good cottages would seem to be one of national importance. The proletariat have made no definite answer to the questions asked at the recent polls that the new Government will owe to such matters as the housing of the rural poor particular attention.

Looking Back.

FROM

THE LANCET, SATURDAY, Jan. 26th, 1826.

A correspondent has favoured us with the following witty prospectus.

"NEW MEDICAL JOURNAL,
On improved Principles.

THE public are respectfully informed, that on Saturday, January 26, 1828, will be published, the first number of a new Medical Journal, to be entitled,

THE ACTUAL CAUTERY.

The great object of the associated editors, is the earliest possible dissemination of 'sound medical and surgical knowledge' throughout the universe; and all contributors may rest assured, that within ten minutes of the first discovery of any fact in medicine, surgery, and the collateral sciences, it shall be put to press, and with all possible haste made known to the public.

The office will be open at all hours for the reception of communications, and the clerk is directed to note carefully, by a stop-watch, the minute at which they are received, in order to ensure to gentlemen the priority of their discoveries.

The name of this Journal will be a sufficient guarantee to the public at large, of the determination of the editors to spare no individual in any department of the profession. They will, however, not be answerable for libels, in a court of law, but have engaged, at a high salary, a gentleman from the sister kingdom, to give all other satisfaction that may be required. Another object of this Journal, is to develop the latent causes of the present convulsed, and distracted state of the profession in this country, on which point the medical world have of late been most grossly misled.

Attached to no party, tools of no junta, organs of no faction, actuated by the purest public spirit, disdaining all reward, save the gratitude of posterity, the determination of the editors is to outstrip the 'March of Intellect,' to set at rest every disputed point in medicine, and to reduce the science to mathematical certainty.

One of the new features of this Journal is, that each number will contain at least two leading articles; the reviews will be spirited; no epigram will be inserted that has not some point; and the lives of eminent practitioners will be given, as soon as they are known to be 'in *Articulo Mortis*.'

Correspondents have been engaged, at a great expense, in all parts of the world, except 'Otaheite,' where arrangements will be shortly entered into with the most distinguished Fellows of the Royal College of Physicians in that country.

N.B. The Journal will be published regularly on Saturday mornings, but may be had in all the shops on Thursday at 2 o'clock. Members of parliament are engaged to frank for country circulation.

P.S. The different colours of the rainbow being already occupied by publications pretending to similar character, the present Journal will appear alternately in a black and white cover, to imitate which will be deemed 'literary plunder.' The unsold copies of this Journal, bound in calf, at the

end of the year, will be distributed among such of the correspondents as have favoured the editors with the longest reports, cases, essays, &c. &c. during that period of time.

* * All communications, for the present, to be addressed to MONSR. TONSON, at our office, *Warrick Street, Golden Square.*"

THE REPORTS OF THE ASYLUMS OF THE WEST RIDING OF YORKSHIRE FOR THE YEAR 1904.

THESE asylums number five, four of which are for the pauper class and the fifth, at Scalebor Park, accommodates private patients. The reports of all are presented now in one volume which opens with a report from the West Riding asylums committee. On the recommendation of this body the county council of the West Riding adopted a resolution in which alarm was expressed at the progressive increase of lunacy in the country and the presentation of a memorial to the Government was agreed to praying that a Royal Commission should be appointed to inquire into the causes of such increase and the steps which should be taken to arrest the same. This memorial was duly presented and a copy of it was sent to the County Councils' Association, the executive council of which adopted much the same resolution as the above. No action was taken by the Government. The total net increase during 1904 of patients chargeable to the Riding was 106. Table No. 1 deals in a very convenient way with the statistics as to admissions, discharges, and deaths in the three old asylums (Wakefield, Wadsley, and Menston) annually for a period of ten years (1895-1904) with annual averages. The admissions during 1904 for the three institutions in the order named were 505, 437, and 378. The annual average percentage of recoveries on admissions for the ten years was respectively 40.07, 40.7, and 39.91. These are satisfactory rates. The percentage of late years at Wakefield is very much the same as at the other asylums, from which it would seem that up to the present the greater facilities for treatment which have of recent years been provided at that asylum have not been productive of better results. It is true that in 1904 the percentage recovery-rate at Wakefield was 44.55 as compared with 39.3 and 35.7 at the other asylums but these figures cover only one year. It is also the case that for 1903 the recovery-rate at Wakefield was 49.9 per cent. as against 35.3 per cent. for county and borough asylums in general. The average number resident in 1904 was for Wakefield, 1811; for Wadsley, 1652; and for Menston, 1595. The annual average percentage of deaths on the annual average number resident during the ten years was respectively 10.97, 11.4, and 11.51, the figures for county and borough asylums for the same period being 10.11.

The average annual increase of the insane of the West Riding in asylums during the past ten years is 128, whereas in workhouses there has been a decrease amounting on the average annually to seven. The usual tables of medical statistics are given for the different asylums; if these could be collated and a summary of the whole provided the result could not fail to be of great value, having regard to the amount of material available. The tables of causation of insanity at the three asylums mentioned are based in two cases upon the statistics of ten years and in the third case of 16 years and are therefore very useful. The percentage incidence of heredity, direct and collateral, is at Wakefield 32.7 and at Menston and Wadsley 22.8 and 23.1 respectively. When it is remembered that the statistics are based upon the admissions of several years this discrepancy between the first-named institution and the others requires some explanation. The population drawn from must be much the same in nature at all three asylums, and it seems not improbable that at Wakefield the histories are more fully inquired into. We notice that "other bodily diseases or disorders" are assigned as causes in 18.1, 19.2, and 23.3 per cent. respectively in the three asylums. It would be of interest to know the kinds of disease which were operative. Alcohol was assigned as a cause in 23.1 per cent. of the Wakefield cases as against 14 and 16 per cent. in the other two asylums.

Turning to the reports of the medical superintendents, we find Dr. J. G. McDowall of Menston Asylum referring to an excess of male patients over accommodation to the extent of

31, which has, however, been largely counteracted by utilizing the infectious hospital for cases suffering from tuberculous disease and diarrhoea, and by a re-arrangement it was found possible to add 16 beds to the accommodation. The asylum being full notice had to be given to the unions that none but acute cases could be received. A much trusted patient who had never exhibited any suicidal tendencies was found kneeling in a bath dead, his face immersed in a few inches of water. Death was, it is thought, due rather to the sudden occurrence of an epileptic fit than to suicide. A coroner's jury considered that the patient drowned himself whilst insane. Another man, who was removed from the asylum contrary to the medical superintendent's advice, killed himself with a razor the day following discharge. Why did the asylum committee discharge the patient contrary to the medical officer's advice? Its consent was necessary if, as we gather, the patient was a pauper. Fortunately, committees very seldom act thus. Two deaths were due to enteric fever and five to "enteritis and colitis." The Commissioners in Lunacy report 34 attacks of dysentery to have occurred since their last visit.

Dr. W. S. Kay of Wadsley comments, as in previous reports, upon the large proportion of hopeless cases amongst the admissions—cases debilitated and paralysed. Colitis was prevalent on the overcrowded male side, several very severe cases occurring, of which 13 died.

At Wakefield the medical superintendent, Mr. W. Bran Lewis, also remarks upon the hopeless character of a large proportion (41.58 per cent.) of the admissions. These cases are tabulated and comprise cases of imbecility, epilepsy, general paralysis, and senile and organic brain disease. This is regrettable considering the unusually good manner in which this asylum is equipped to deal with curable cases. A large proportion of harmless and senile cases crowds up the available space; these might be in the union infirmary or with their friends. The admission-rate of senile cases is shown to be not at all excessive but they tend to accumulate. In his last report Mr. Lewis discussed at length the pathology of colitis or asylum dysentery and opposed the ordinary views which regard this disease as caused by defective sanitation, overcrowding, dietetic defect, or these conditions combined. Whilst not contesting the fact that a specific organism is present he considers that the intestinal tract is rendered vulnerable to this by the chronic constipation which he believes to be present in these cases and which is brought about by atony and torpor of the bowel wall. Mr. Lewis has put to the test the method of prophylactic treatment, by the administration of regular doses of saline aperient, which he referred to in the last report, and the figures which he gives, and which cover the period from April, 1902, to July, 1905, are certainly striking and show a great diminution in the number of cases of the disease since treatment was begun. A more prolonged experience, supplemented by the experience of other asylums, should be most instructive. At the hospital for acute cases of this institution good work is in progress. Hydro-electric treatment in the form of the sinusoidal current gives satisfactory results; we find that of 54 cases treated in 1903 and 1904 and almost entirely composed of persons in states of mania, melancholia, and stupor, 35 recovered and eight were relieved. Mr. Lewis considers the electric bath a most useful accessory to treatment, especially in cases of melancholia and stupor; and this is the experience of certain other alienists. But before these results can be viewed in their true light we require a series of control cases which shall have been submitted to the ordinary "expectant" treatment of asylums and treatment by the warm bath without electricity. Static electricity and high-frequency methods are also employed; of 20 cases so treated in 1903 and 1904 11 are reported to have recovered and four were relieved. Here, again, cases of melancholia and of that state with stupor appear to be best adapted for treatment. Actino-therapy (the x rays and lupus lamp) has been employed for lupus and rodent ulcer with gratifying results. This asylum has an idiot and imbecile department with accommodation for 70 male cases, which was reported full in 1903. It is proposed to provide similar accommodation for imbecile girls at one of the asylums. Special teaching is given to weak-minded children in this department with good results, as instanced by cases reported. The plan ought to be followed widely in asylums. Mr. Lewis advocates a custodial home of this kind for each large county or group of counties from which if

ufficiently improved the children might be removed to a county industrial colony. The out-patient department of the asylum shows much activity, 200 cases being under treatment, a very large proportion of whom suffered from epilepsy and associated nervous and mental disturbances. Good work continues to be done in the pathological laboratory. The report shows that the work of this institution continues to be pervaded by the same scientific spirit and actuated by the same high ideal which have so long procured for it a distinguished position.

In June, 1904, the fourth county asylum for the West Riding was opened at Storther's Hall, Huddersfield. Dr. T. S. Adair, the medical superintendent, reports that at the close of that year 132 patients were in residence, having been received mainly from the sister asylum at Wadsley. From the report of the Commissioners in Lunacy we find that a hospital for acute cases with four wards on each side, to accommodate 104 patients of each sex, has been provided at this asylum, from which we conclude that the asylums committee thinks favourably of this plan which it put into practice first at Wakefield. In this hospital the proportion of nursing staff to patients for day duty will be the high one of 1 to 5.

The third annual report of the West Riding asylum for private patients at Scalebar Park is presented by Dr. J. R. Gilmoor, the medical superintendent. The average number resident daily was 108, as compared with 62 in 1903. 119 patients were in residence at the close of 1904, during which year 112 were admitted. The recovery rate on the admissions was 26.19 per cent. for the males and 48.57 per cent. for the females; the female cases were of a more favourable class for treatment. Of the 13 deaths none was due to tuberculosis. Heredity of insanity was present in 28 of the admissions. 95 per cent. of the patients were paying from 25s. to 42s. per week. The lowest scale of payment was 25s.

VITAL STATISTICS.

ANNUAL BIRTH-RATES AND DEATH-RATES FROM THE SEVEN CHIEF EPIDEMIC DISEASES IN ENGLAND AND WALES DURING 1905.

	Annual rates per 1000 living.			Infant mortality— Annual death- rate of infants under one year per 1000 births.
	Births	Deaths from all causes.	Deaths from seven chief epidemic diseases.	
England and Wales	27.2	15.2	1.52	123
76 great towns	25.2	15.7	1.68	140
141 smaller towns	26.9	14.4	1.50	132
England and Wales less the 217 towns	25.3	14.9	1.09	115

NOTE.—These rates are subject to revision.

We are indebted to the Registrar-General for the above death-rates for the urban and rural areas of England and Wales in the year 1905. We publish them for the information especially of medical officers of health who require these data for the compilation of their annual reports.

HEALTH OF ENGLISH TOWNS

In 76 of the largest English towns 6034 births and 4800 deaths were registered during the week ending Jan. 20th. The annual rate of mortality in these towns, which had been 17.4, 16.2, and 16.7 per 1000 in the three preceding weeks, further declined last week to 15.8 per 1000. In London the death-rate was 15.5 per 1000, while it averaged 16.0 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 5.7 in Southwick, 7.3 in Walthamstow, 8.6 in King's Norton, 8.9 in Burton-on-Trent, 9.4 in Willesden and in Portsmouth, 9.6 in Hornsey, and 10.1 in Leyton; the highest rates were 19.4 in Hastings, 19.5 in Merthyr Tydfil, 20.2 in Birmingham and in Liverpool, 21.1 in Newport (Mon.), 22.1 in Swansea, 24.3 in Sunderland, and 28.2 in Preston. The 4500 deaths in these towns last week included 169 which were attributed to the principal infectious diseases, against 465, 454, and 283 in the

three preceding weeks; of these 369 deaths, 108 resulted from measles, 92 from whooping-cough, 60 from diphtheria, 49 from scarlet fever, 36 from diarrhoea, 23 from "fever" (principally enteric), and one from small-pox. No death from any of these diseases was registered last week in Hastings, Great Yarmouth, Burton-on-Trent, Wolverhampton, Walsall, King's Norton, Coventry, Grimsby, Barnley, York, or Tynemouth; among the other towns the highest death-rates from the principal infectious diseases were recorded in Tottenham, Reading, Handsworth (Staffs.), West Bromwich, Blackburn, Preston, and Gateshead. The greatest proportional mortality from measles occurred in Tottenham, Blackburn, Preston, Leeds, and Swansea; from diphtheria in Wallasey, St. Helen's, and Stockton-on-Tees; from whooping-cough in Reading, Plymouth, Handsworth (Staffs.), West Bromwich, Aston Manor, and Gateshead; from "fever" in Northampton; and from diarrhoea in Middlesbrough. The mortality from scarlet fever showed no marked excess in any of the large towns. One death from small-pox was registered last week in Bristol, but not one in any of the other 76 large towns; and no cases of this disease were under treatment last week in the Metropolitan Asylums Hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 3066, against 3446, 3299, and 3062 at the end of the three preceding weeks; 328 new cases were admitted during the week, against 295, 291, and 257 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 426, 454, and 369 in the three preceding weeks, further declined last week to 299 and were 71 below the corrected average number in the corresponding periods of the four preceding years. The causes of 54, or 1.1 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Nottingham, Salford, Bradford, Leeds, Hull, Newcastle-on-Tyne, and 48 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Rochdale, Blackburn, Preston, Middlesbrough, Sunderland, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 18.2, 19.8, and 17.8 per 1000 in the three preceding weeks, rose again to 18.2 per 1000 during the week ending Jan. 20th, but was 2.4 per 1000 in excess of the mean rate during the same period in the 78 large English towns. The rates in the eight Scotch towns ranged from 11.4 in Paisley and 13.9 in Leith to 18.7 in Glasgow and 22.8 in Dundee. The 624 deaths in these towns included 24 which were referred to measles, 19 to diarrhoea, five to diphtheria, three to scarlet fever, and two to whooping-cough, but not any to small-pox or "fever." In all, 53 deaths resulted from these principal infectious diseases last week, against 65, 80, and 61 in the three preceding weeks. These 53 deaths were equal to an annual rate of 1.5 per 1000, which was 0.3 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of measles, which had been 25, 33, and 28 in the three preceding weeks, further declined last week to 24, of which 19 occurred in Glasgow and three in Dundee. The deaths from diarrhoea, which had been 14, 20, and 16 in the three preceding weeks, rose again to 19 last week, and included eight in Dundee, five in Glasgow, four in Aberdeen, and two in Edinburgh. The fatal cases of diphtheria, which had been 12, 13, and eight in the three preceding weeks, further declined last week to five, of which two were registered in Perth. The deaths from scarlet fever, which had been two in each of the two preceding weeks, increased last week to three, all of which occurred in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 99, 126, and 126 in the three preceding weeks, further declined last week to 114, and were 42 below the number in the corresponding period of last year. The causes of 21, or more than 3 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 21.7 per 1000 in each of the two preceding weeks, declined to

20.1 per 1000 during the week ending Jan. 20th. During the past four weeks the death-rate has averaged 20.4 per 1000, the rates during the same period being 17.6 in London and 17.2 in Edinburgh. The 146 deaths of persons belonging to Dublin registered during the week under notice were 12 below the number in the preceding week and included three which were referred to the principal infectious diseases, against seven, six, and seven in the three preceding weeks; of these, one resulted from scarlet fever, one from whooping-cough, and one from diarrhoea, but not any from small-pox, measles, diphtheria, or "fever." These three deaths were equal to an annual rate of 0.4 per 1000, the death-rates last week from the principal infectious diseases being 1.2 in London and 0.6 in Edinburgh. The 146 deaths in Dublin last week included 28 of children under one year of age and 38 of persons aged 60 years and upwards; the deaths of infants showed a slight decline, while those of elderly persons exceeded the number in the preceding week. Five inquest cases and six deaths from violence were recorded, and 54, or more than a third, of the deaths occurred in public institutions. The causes of six, or more than 4 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

VARICOCELE AND CANDIDATES FOR THE ARMY.

We understand that the discussion with regard to varicocele as a disqualification for army candidates which has recently taken place in THE LANCET and the service newspapers has had the effect of inducing the authorities to modify the rules which have hitherto been in force. The text of the new regulations has not yet been published, but there is every reason to believe that the proposed alterations will lead to the acceptance by the Army Medical Board of many candidates who would have been disqualified under the old rules.

ROYAL NAVY MEDICAL SERVICE.

In accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1881, Fleet-Surgeon Everard Home Saunders has been placed on the Retired List at his own request, with permission to assume the rank of Retired Deputy Inspector-General of Hospitals and Fleets (dated Jan. 18th, 1906).

The following appointments are notified:—Staff Surgeons: G. A. S. Bell to the *Monmouth* and H. Spicer to the *Cornwall*. Surgeons: A. C. W. Newport to the *Gladiator* and H. B. German to the *Argyll*.

COLDSTREAM GUARDS.

Surgeon-Lieutenant-Colonel Warren R. Crooke-Lawless is seconded for service on the Staff of the Viceroy and Governor-General of India (dated Nov. 2nd, 1905).

ROYAL ARMY MEDICAL CORPS.

Colonel Jules I. Routh is placed on temporary half-pay on account of ill-health (dated Jan. 8th, 1906). Lieutenant-Colonel Robert H. Forman to be Colonel, vice J. I. Routh (dated Jan. 8th, 1906). Major John H. Rivers, from the Seconded List, to be Major (dated Jan. 17th, 1906). Captain Hamilton G. F. Stallard, from the Seconded List, to be Captain (dated Jan. 7th, 1906).

Lieutenant-Colonel C. W. Johnson joins at Woolwich. Captain H. G. F. Stallard, attached to the Egyptian Army, is posted to the Eastern Command for duty at Woolwich. Major C. H. Melville, Sanitary Officer, Army Headquarters, India, is appointed an Expert in Sanitation on the Advisory Board.

Lieutenant-Colonel Alfred Peterkin is granted the local rank of Colonel while serving in Mauritius (dated Nov. 22nd, 1905). Lieutenant-Colonel George D. Hunter, D.S.O., is granted the local rank of Colonel whilst employed with the Egyptian Army (dated Jan. 24th, 1906).

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain John M. Moir to be Surgeon-Major (dated Jan. 13th, 1906).

ROYAL ARMY MEDICAL CORPS (MILITIA).

Denis Murphy to be Lieutenant (dated Jan. 24th, 1906).

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 1st Midlothian: The undermentioned officers resign their commissions:

Surgeon-Captain A. A. S. Skirving, O.M.G. (dated Jan. 24th, 1906); Surgeon-Captain (Honorary Lieutenant in the Army) W. M. Taylor (dated Jan. 24th, 1906).

Rifle: 3rd (Cambridgeshire) Volunteer Battalion the Suffolk Regiment: Supernumerary Surgeon-Captain F. E. A. Webb is absorbed into the Establishment (dated Nov. 1st, 1905). 2nd Volunteer Battalion the East Yorkshire Regiment: Surgeon-Captain (Major, Volunteers, retired) J. Chestnutt is granted the honorary rank of Surgeon-Major (dated Jan. 24th, 1906). 5th (Glasgow Highland) Volunteer Battalion the Highland Light Infantry: Supernumerary Surgeon-Major Q. Chalmers (Brigade-Surgeon-Lieutenant-Colonel, Senior Medical Officer, Highland Light Infantry Volunteer Infantry Brigade) to be Surgeon-Lieutenant-Colonel, remaining Supernumerary (dated Jan. 24th, 1906). 4th (Stirlingshire) Volunteer Battalion Princess Louise's (Argyll and Sutherland Highlanders): Peter McFadyen to be Surgeon-Lieutenant (dated Jan. 24th, 1906).

DEATHS IN THE SERVICES.

Deputy Inspector-General Walter Frederick Cope Bartlett on Jan. 14th at Plymouth. He entered the service as surgeon in 1856 and was promoted to fleet surgeon in December, 1877, retiring in June, 1887, with the rank of deputy inspector general of hospitals and fleets. He was assistant surgeon of the *Raleigh* when she was wrecked off the China coast in April, 1857. He afterwards served in the hospital ship at Hong-Kong during the China war, 1857-60 (medal), and was fleet surgeon of the *Agincourt* during the Egyptian war in 1882 (medal and Khedive's bronze star).

APOTHECARIES IN THE GERMAN ARMY.

The pharmaceutical department of the German army was reorganised in 1902. In Germany medical and pharmaceutical students are allowed to perform the military duty which is incumbent upon all able-bodied adolescents of the male sex by volunteering for one year, but before they can claim this privilege they have to produce a certificate of aptitude for military service from a board appointed by the State and must also undertake to equip, to clothe, and to maintain themselves at their own expense. Military apothecaries on the permanent list are recruited from these volunteers. When the new organisation came into force they were 49 in number, all classed as officers, although their relative rank was not defined, but when the new scheme is completed their strength will be considerably increased. The official title of the chief of the department is Oberstabsapotheker. He is attached to the medical section of the War Office, where he deals with the technical questions appertaining to his specialty and also controls all military pharmacies whether they belong to the active army or to the reserve. Next in rank are the Korpsstabsapotheker, 24 in number. One of these officers is attached to each of the 23 army corps into which the German army is divided. Under the orders of the principal medical officer he is responsible for the efficiency and good order of everything connected with his department, his duties including the bi-annual inspection of every pharmacy in the command, the control of supply and expenditure in these establishments, the auditing of their accounts, the superintendence of subordinates not only with the colours but also in the reserve, and the direction of the analytical laboratory with which every army corps is provided. The officers of the third grade are designated Stabsapotheker, and in 1902 they too were 24 in number. The duties of a Stabsapotheker consist in superintending the sanitary depot of the army corps to which he belongs and in managing the pharmacy of the garrison hospital at headquarters. According to the reorganisation decree of 1902 every military hospital with 71 beds and upwards should have a Stabsapotheker in charge of its pharmacy, but this part of the scheme has not as yet been carried out. The pharmaceutical students serving for a year as volunteers are distributed according to requirements among 120 hospitals to the number of 265, some of them doing additional duty in the laboratories and sanitary depôts. There are also five more serving in the Kaiser Wilhelm Academy at Berlin under a Korpsstabsapotheker, which brings the total strength up to 270. After serving for six months a volunteer student may be permitted to return to his home in order that he may complete his professional education and obtain a diploma. He then has to resume military duty for a second period of six months and, should he be desirous of joining the permanent branch, must next go through a special course of six

weeks' duration to the satisfaction of the principal medical officer. Having surmounted this test the student has then to go through a course of analytical chemistry, with special reference to water and alimentary substances, in a Government laboratory. The duration of this course is 18 months and at the end of it the candidate has to satisfy a board of examiners. Ability to carry out analyses was rendered obligatory in 1902 for all the apothecaries who were then serving and all desirous of remaining in the department were obliged to provide themselves with the State diploma. The relief of military medical officers from more or less uncongenial work in the superintendence of pharmacies is a distinct step in advance but as yet the reform is incomplete. In all hospitals of less than 71 beds the medical officer is supplied with a limited stock of simple medicaments of which he has to control the distribution. Should more complicated medicine be required he must have recourse to the civilian pharmacy of the locality. The fact that the total strength of the pharmaceutical department of the German army in 1894 was only 217 of all ranks, whereas in 1904 it was 321, is of good augury that in time all military medical officers will be relieved from pharmaceutical duty. The details given above are taken for the most part from an article by Apothecary-Major of the First Class Kopp in the *Archives de Médecine et de Pharmacie Militaires* for December, 1905.

SELF CONSTITUTED JUDGES.

It is reported in the *Syn Otetchestvo* that a marine of the warship *Georgia Pobedonozca*, named Mlachotin, who was under observation in the Cronstadt hospital as a patient presumed to be insane, has been ordered before a court by the medical specialists in attendance with the observation that "he is a sly malingerer meriting sentence of death." No doubt, adds the journal quoted, this extraordinary assumption of juridical prerogative will be inquired into. It is an inversion of what usually occurs, for as a rule it is the intervention of the medical man which prevents a sick man from being treated as a responsible criminal.

MILITARY HYGIENE ON ACTIVE SERVICE.

At the Royal United Service Institution on Jan. 18th Surgeon-General A. Keogh, C.B., M.D.R.U.I., Director-General A.M.S., presided at the lecture given by Major T. H. J. C. Goodwin, D.S.O., R.A.M.C., on *Military Hygiene on Active Service*. Several officers took part in the interesting discussion which followed.

Correspondence.

"Audi alteram partem."

PHYSIOLOGICAL TESTS FOR PHARMACEUTICAL PREPARATIONS.

To the Editors of THE LANCET.

SIRS,—As my name has been quoted in the letters which have appeared on physiological tests for drugs may I briefly state the conclusions to which I have been led. We know that plants vary considerably in the amount of the active constituents which they contain; season, soil, climatic conditions, &c., all tend to modify the percentage of toxic principle. The British Pharmacopœia fully recognises this fact and has determined that, as far as possible, all potent galenicals shall be made to contain a definite amount of active substance—that is, they must conform to a chemical standard. It is not possible to determine the amount of active principle in certain drugs by chemical means, because their chemistry is too ill-defined; such drugs are those of the digitalis group, ergot, Indian hemp, and a few others. Moreover, it is just these drugs which exhibit the widest variations in physiological activity and hence the introduction of bio-chemical tests, which form an accurate means of determining the amount of active principle present. Dr. Haynes and myself have clearly shown that the activity of the drugs mentioned varies within the widest ranges. To take a single example, that of ergot, which is quoted by your correspondent, Dr. William Martin. We have shown, though we have not yet published, that the preparations of this drug, as sold by the leading wholesale houses, vary enormously in potency; and further, that preparations which we have ourselves

made from different samples of the crude ergot show the same variability. It must be a matter of general regret that such important drugs as those named should be so variable in action; and the importance of putting into the hands of the physician a remedy which will produce the effects it is reputed to have, cannot be over-estimated. Yet the fact remains that much of the ergot at present sold is useless. We hope at an early date to put the case of ergot more clearly before the profession.

I am, Sirs, yours faithfully,
W. E. DIXON.

Pharmacological Laboratory, Cambridge, Jan. 23rd, 1906.

To the Editors of THE LANCET.

SIRS,—In the letter from Dr. W. Martin in your issue of Jan. 20th, I note that your correspondent suggests that too much emphasis is being laid on the physiological testing of drugs and that he disagrees with the suggestion that a central laboratory should be established for such testing. He gives as his reasons: (1) That it has not been proved that bio-chemical methods are of vital importance; and (2) that it has yet to be proved that if they are of vital importance private enterprise and effort are unable to deal with them.

With regard to the first point, I may refer your correspondent to the opinion of Dr. Barger and Dr. W. Vernon Shaw who, in the course of an exhaustive paper on the Chemical and Physiological Assay of Digitalis Tinctures, submitted to the British Pharmaceutical Conference at Sheffield and reported in the "Year Book of Pharmacy, 1904," p. 541, made the following statement as the result of their work: "As yet the only reliable method for the assay of digitalis tincture is the physiological one." Dr. Dixon Mann in the course of last year is reported to have stated that "few medicinal preparations vary so much in activity as do those of digitalis. It is not to be denied that much of the ordinary tincture of digitalis is inert or thereabouts." I think these statements, which could be easily multiplied tenfold, should suffice to cause any conscientious chemist to recognise the importance of standardising such preparations by physiological means.

With regard to the second point, it is practically impossible, at least in this country, for private enterprise and effort to deal with such matters. The testing could only be performed by licensed vivisectioners, and it is essential that it should be performed under proper supervision in public laboratories.—I am, Sirs, yours faithfully,

Exeter, Jan. 22nd, 1906.

H. WIPPELL GADD.

WHY DO ANIMALS CRY IN PAIN?

To the Editors of THE LANCET.

SIRS,—Assuming it is entirely beyond question that the use of communication can be regarded only as a secondary function of the cry of pain I propose to come at once to close quarters with the problem of the primary function of the cry by putting the following question. Has the cry animals utter in consequence of shock (in the form of pain, surprise, fright, &c.) any psychological value because of the sensory stimuli which, so to speak, double back upon the animal's own motor, co-ordinating, and psychical nerve centres, from the muscular movement of the vocal apparatus and from the sounds of the cry?

A first step toward answering this question will be to note the deep-rooted prerogatives which sounds, especially vocal sounds, possess for the stimulation of motor and psychical nerve centres. We may pass by the unique stimulating power of the spoken word because it is intimately bound up with the uses of communication and is exclusively human, and take the sounds of music. Here, at once, human experience and the behaviour of birds under the influence of the music of their family or tribe leave no doubt about the special stimulating power of vocal sounds, whether in musical forms or in the character of broken cries, over motor and psychical functioning. Now the results of zoological research into the genesis of the organs of hearing, in supporting other indications of the prerogatives of vocal sounds over motor and psychical functioning, also, at the same time, distinctly warn us away from the supposition that these prerogatives are a mere consequence of the use of the voice for communication. It is shown that in their rudimentary forms organs of audition

The streets are broader and the houses less high. Large quantities of porter are drunk which suggests a question as to possible relation of this to the ability to suckle children. The whisky was not of the fiery order but was conspicuously advertised as malt. One sees hockey, football, &c., in full swing in the public parks about Dublin on Sunday. I have been induced to state these observations by reading your comment. I had supposed they were matters of common knowledge. I do not attempt any deductions but these observations suggest that inquiry might be fruitful. In conclusion, if the conditions of life in Dublin favour low infantile mortality, why is the death-rate from tuberculosis so high?

I am, Sirs, yours faithfully,

INQUIRER.

Jan. 16th, 1906.

TUBERCULOSIS AND THE NORTHAMPTON BOOT TRADE: A PROPOSED SANATORIUM.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

(Concluded from p. 185.)

THE proposal that the town of Northampton should build a popular sanatorium was adopted at a moment when unfortunately several town councillors were absent. Consequently it has been regarded as of the nature of a snatch vote and the council has to some extent gone back upon its decision. Indeed, it is easy to see that the whole question is viewed with considerable apprehension. A great meeting was held at Northampton on Nov. 1st, when Councillor J. Manfield, J.P., a candidate for the Mayoralty, delivered a lengthy speech practically in opposition to the resolution adopted by the town council on Sept. 5th in favour of the erection of a sanatorium. He recognised that corporations had the right to take steps for the prevention of tuberculosis but was in doubt as to what were the best steps. He declared that attempts to deal with this matter by public bodies were in an experimental stage. To this it might be answered that every year some 30,000 patients are received in the sanatoriums created by the German authorities and that this constituted something more than an experiment. Also, it might further be urged that if experiments have to be made surely it is those towns where the disease is exceptionally prevalent that have the more reason to make the first experiments. Against this latter argument it may, however, be objected that it is specially the workers in the boot trade and not the inhabitants of the town as a whole who are disproportionately afflicted with tuberculosis. It might be suggested that before the town as a whole is burdened with the expense of building a sanatorium the owners of the boot factories should be compelled to incur the expense of ventilating their factories properly. The Public Health Act of 1878, as improved by the Act of 1891, places such workshops and factories under the care of the local authority. If the local authority fails to act in this respect the Secretary of State may authorise the factory inspector to take whatever action is necessary and to charge the same to the local sanitary authority. Section 32 stipulates for the maintenance of a reasonable temperature in each workroom and it is not reasonable to expect a worker to sit or stand all day long in the draught caused by an open window. On the other hand, the Act insists on sufficient ventilation and air space. It is impossible to repeat too often that this can only be obtained by mechanical means scientifically applied. The air inlets must be arranged over such an extended surface that the air shall not travel at a greater velocity than about one foot per second. There would, then, be no further complaints as to draughts.

In the meanwhile and before perfect hygiene and ventilation are established in all the factories and workshops many thousand cases of pulmonary tuberculosis will occur for which provision should be made. If in some distant future there is a good time coming when all poverty and insanitary conditions having been abolished there shall be no more tuberculosis, sanatoriums will still be of use as ordinary convalescent homes, or schools, or holiday resorts for children, and many other purposes. Therefore, the hope that in regard to tuberculosis they may ultimately become useless need not retard their immediate construction.

To return to Councillor Manfield and the Northampton corporation, considerable capital is made of the argument that it is more useful to treat advanced cases than those cases which, taken at the earliest stages, offer some hope of cure. The idea, of course, is that the advanced cases spread the disease and that contagion would be prevented if they could be removed from their homes and isolated. But it would be much more satisfactory if it were possible to believe that this argument was purely a scientific argument and was in no wise connected with financial considerations. Councillor Manfield, however, very frankly not only admitted, but even urged as an inducement, that a building for advanced cases might be obtained without great cost just outside the town. Here "simple, plain, comfortable accommodation would be all that would be required," and he had previously insisted that "no elaborate sanatorium would be required for this purpose." While thus betraying how deeply he was actuated by financial considerations, the speaker seemed to forget that the patients themselves would be influenced by quite different feelings. As it is not proposed to employ compulsion, such feelings are of practical importance. Now it is quite obvious that a person still actuated by the boy's hopefulness of youth would gladly leave his friends and go to an "elaborate sanatorium" so as to free himself from the menace of a fatal disease. It is not so certain that a patient in the last stages of a disease which had become incurable would as willingly leave his relatives and friends and go to die in a "simple, plain" hospital for the hopeless. Has it occurred to the advocates of this system to consider for a moment the feelings of those persons who are to be removed to this house for the dying? It is strange to have to recommend the corporation of so advanced a town as Northampton to look for an example on this phase of the question to, for instance, the Danubian principalities. At Bucharest a large sanatorium has been built where in separate buildings and on a vast estate tuberculosis in all its stages is treated. Here care is taken that there shall be nothing to show the patient that his case is considered hopeless. Yet the Roumanians, who have only of recent years become an independent nation, are not wealthy like the inhabitants of Northampton. Nor are they placed in the vanguard of civilisation—a position which British subjects often boast of occupying.

On Dec. 4th last the question came up for discussion once more and the sanitary committee reported to the town council that the purchase of a site and the erection of a sanatorium to hold 40 beds would cost about £14,000. This is £350 per bed, or something like £100 to £150 in excess of the more general estimates. For instance, the very elaborate Basle popular sanatorium at Davos-Platz, where the building materials had to be carried up to a height of over 5000 feet above the sea, cost £263 per bed, and the much more simple Dutch sanatorium, also at Davos-Platz, only cost £150 per bed. The estimate for the yearly outlay seems much more reasonable—namely, £3200, or £80 per annum per bed. Apprehending that a sanatorium would cost too much, the sanitary committee recommended that selected cases should be sent to other sanatoriums already established in the country. The difficulty rests, however, in this very fact that there are hardly any popular sanatoriums in England. If there had been a plentiful supply of such institutions we should not have had the Sandgate scandal. At the Paris International Congress on Tuberculosis the medical officer of health of Brighton, Dr. A. Newsholme, stated that in the London hospitals devoted especially to the treatment of lung diseases there were only 655 beds; in the provinces there were 414 beds, in Scotland 41, and in Ireland 64 beds. As more than 56,000 persons die from pulmonary tuberculosis in Great Britain during the course of the year, neither the hospitals nor the sanatoriums that exist are anything like sufficient to provide the accommodation needed. Therefore Dr. Newsholme had to explain that in England the only action in regard to the removal from their homes and the treatment of cases of pulmonary tuberculosis which had been taken on a sufficiently extensive scale materially to reduce the prevalence of that disease was the reception, and incidentally the isolation, of tuberculous paupers in the workhouse infirmaries. Practically little or nothing else is done in regard to treatment and isolation of cases of pulmonary tuberculosis.

The reduction, amounting to some 50 per cent., in the prevalence of tuberculosis which to our great honour has been realised in this country is the reward of general

sanitary and economic improvements and not of any special measures for the treatment of that disease. Indeed, it is in view of this magnificent result that in criticising the position at Northampton the first care taken was to point out that further sanitary improvements were needed in the trade where an exceptionally large number of cases occurred. If the corporation is so very anxious to avoid spending money, then by far the cheapest way to reduce the prevalence of tuberculosis is to compel the boot manufacturers to warm and to ventilate properly their factories and workshops.

The sanitary committee, having pointed out that it would be very expensive to build a sanatorium, proposed that the Walford-road Borough Hospital, which used to be employed for isolation purposes, should be opened for the reception of ten advanced cases. But Dr. Beatty, the medical officer of health, has pointed out that the number of deaths from pulmonary tuberculosis registered at Northampton in 1904 amounted to 104 and in 1903 to 114. To this Dr. Beatty adds: "The proportion of living consumptives in any one year to those who die in the same period is between three and four to one, therefore in the town during the year 1904 there must have been about 260 cases, and of these 71, or less than 20 per cent., were notified." According to these figures, therefore, it is not ten but about 100 patients who should be removed to a hospital if they have not sufficient house room to isolate themselves in their own homes. As it is the workers in the boot and shoe trade who are the principal victims it is quite obvious that the great majority are not able to isolate themselves properly. Therefore the provision of ten beds for patients to die in is just about the very smallest little bit of tinkering with the subject that could possibly have been attempted.

Even the proposal to build a sanatorium for 40 beds which seems to have caused so great an alarm is altogether inadequate. It would be much cheaper to build a sanatorium for from 100 to 200 beds. The greater the number of beds the greater the extent of the surrounding estate, pine wood forests, &c., if the same sum per bed was spent on the purchase of land. The cost of administration and management is also cheaper per head the larger the number of persons concerned. The figures given show that Northampton itself could supply far more than 40 patients. But there is such a complete dearth of popular sanatoriums in this country that the town council of Northampton could easily obtain from other local authorities patients at a rate which would help to defray the expense incurred. For local authorities to send patients to some speculator who is making a trade of the outdoor treatment of tuberculosis is to incur a very serious responsibility. But it is most natural that the capital of a county should take the initiative and should offer to the surrounding smaller localities the use of a sanatorium built and managed under public control for the public good and not as a private speculation. Such an initiative would receive very wide support and the outlay would be more than recouped by the direct and indirect benefits that would accrue. If this suggestion seems too venturesome and bold there is nevertheless nothing novel or untried about it. For instance, it is now three years since the *Députation Provinciale* or County Council of Liège completed, at a cost of £52,000, its magnificent sanatorium among hills and forest at Borgoumont. Here there are 114 beds and it is a palatial structure situated at an altitude of 415 metres, with a façade of 146 metres, covering 3519 square metres, and with a cube contents or measurement of 23,800 cubic metres. The sun-bathed verandahs, the broad corridors within, the rooms, each with a wall all window space, the majestic valley that stretches out in front, the verdure of the surrounding mountains and forests, the ideal character of the site, the luxury of the building, the excellent results already obtained with the patients, are all things that have to be seen before the puny character of the proposals made to the Northampton town council can be adequately appreciated. Why should Northampton hesitate when Liège has led the way and with so much success? Nor need Northampton be alone in the matter. It would be better to act in consort with the entire county, for a sanatorium is more economical when built on a large scale. Also, an arrangement might be made with some of the friendly societies. It would be to their financial advantage to pay for the keep and treatment of some of their members in a sanatorium. But even if the cost of the maintenance of

all the patients was paid for out of the rates that cost would be reduced if it came from the rates of more than one borough or locality. Then it must be borne in mind that whatever is done in this direction will tend first and foremost to reduce the sum total of human suffering; secondly, it will increase the labour capacity and therefore the wealth of the community; and, finally, it will bring about a reduction in the poor rates. Of course, it is obvious that the building of a sanatorium does not alone suffice. At least, four different sorts of institutions are needed. First, there should be a dispensary and investigation department combined. To this a large staff of voluntary workers should be attached. Their mission would be to find out where the sanitary laws which help to prevent tuberculosis are not applied and to get evidence against the delinquents. Then they should discover cases of tuberculosis and bring them to the dispensary where the medical officer would examine them and decide what was to be done. In this respect there should be at least three different methods available. First the preventive method, applicable especially to children, consisting of out-of-door schools and treatment, such as exist already at Berlin and many other towns, especially in Germany. Then, secondly, the curative out-of-door treatment for cases in the earliest stages, that is to say, the sanatorium proper. Thirdly, there should be the hospital treatment for the advanced and almost hopeless cases and the chief advantage secured here is the isolation of patients at the time when they are most likely to spread the disease. The special anti-tuberculosis dispensary serves then to discover and to sift the cases; to decide to which of the three great divisions in treatment they properly belong. It also serves as a centre from which the patients who have come back from the sanatorium can be watched and made to carry out strictly the instructions which they have received. This is a somewhat wider programme than the provision of ten beds in a disused hospital for infectious diseases; and this is what Northampton and other English towns will have to do if they wish to be on a level with Berlin and many other continental towns and cities.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The University.

THE second term of the winter session commenced on Jan. 16th and all departments are again in full work. Unfortunately, the Principal, Sir Oliver Lodge, is absent. He was seized during the holidays with an attack of influenza character which confined him to bed for a considerable time and when he became convalescent his medical advisers insisted that he must go to Italy for several weeks.—The anatomical department has lost Dr. W. Wright who has been appointed lecturer on anatomy at the *Middlesex Hospital*. Dr. Wright came to Birmingham about five years ago, being appointed from the junior demonstratorship of anatomy in the Owens College to the senior demonstratorship in Birmingham. During his tenure of office he made many friends who now regret his departure and are preparing to celebrate his advance to an independent post by a complimentary dinner to be given during the course of next month.—A long-felt want in Birmingham is about to be satisfied by the erection of a 300-ton testing machine in the engineering department in the new buildings at Bournebrook. The money for this great instrument was secured by the energy of Mr. Joseph Chamberlain, the Chancellor of the University, and the acquisition of the instrument will be greatly appreciated by the manufacturers in the neighbourhood.

Local Charities.

The will of the late Mr. Probin Ward provides for the division of £550 between the following 11 local charities, £50 to be given to each: The Birmingham General Hospital, the Queen's Hospital, the Orthopaedic Hospital, the Eye Hospital, the Children's Hospital, the Ear and Throat Hospital, the Blue Coat School, the Institution for the Blind, the Institution for the Deaf and Dumb, the Women's Hospital, and the Birmingham Dispensary; and the late Mr. William Robert Lane has left £1000 each to the Birmingham General Hospital, the Queen's Hospital, and the Children's

Hospital.—An attempt has been made to start an agitation for bringing the hospitals under municipal control by a complaint, published in the correspondence columns of a local paper, that the nurses in one of the hospitals were overworked and by a suggestion that their working hours should be limited to eight. The writer urged that other reforms were also necessary but, as is usual with agitators, he overstated his case by asserting that at the present time the hours were 12½ and 11½ on alternate days, whilst the reply of the secretary of the hospital shows that the staff nurses work 10 hours, the assistant nurses 10 and 10½ hours, and the probationers 10 and 11 hours on alternate days.—The quarterly report of the Birmingham and Midland Eye Hospital demonstrates that the institution is doing a very large amount of useful work. The total number of patients under observation during the period was 6846, of which 261 were in-patients and 6385 were out-patients. Over 2000 out-patients and 73 in-patients were treated without tickets on account of their urgent need. During the quarter 329 operations were performed, 65 patients were provided with glass eyes, and 2480 with spectacles.

The City of Birmingham Aid Committee.

In the past it has been the custom in Birmingham, as in many other cities, that each of the local mutual aid societies should have its own organisation. Where centralisation occurred it was merely for the purpose of keeping the various organisations in touch with each other. It has now been decided to form a combination consisting of a central body of which the various mutual aid societies will form branches. The work in future will be carried out by a central executive committee, seven branch committees working in different sections of the city, and as many district helpers' committees as may be necessary for the proper working of each branch. The executive council will consist of the Lord Mayor, as president, if he is willing to serve; the chairman, the honorary secretaries and treasurers of the branch committees; two additional representatives from each branch committee; a representative from each of the Birmingham, Aston, and King's Norton boards of guardians; a representative of the distress committee under the Unemployed Workmen's Act, 1905; a representative of the Charity Organisation Society; a representative of the Women's Settlement; a representative of the Birmingham trades council; and other persons possessing special knowledge, co-opted from time to time by the council. The funds are to be raised by a finance committee consisting of the honorary treasurers of the branches and they will be controlled by the executive council. The step which has been taken is expected to be more than fully justified, for, as a result, the work will be better organised and controlled and subscribers to the funds will be able to feel certain that everything will be well managed. The scheme corresponds with the Elberfeld system in many respects but it is not quite so democratic.

Underfed Children.

Some misunderstanding and a little friction have arisen in the district in association with underfed children and the chairman of the Birmingham School Cheap Dinner Society, the Rev. E. F. M. McCarthy, has written to the Birmingham and Aston boards of guardians stating that the business committee of his society has decided to discontinue the supply of dinners for the present and, further, that his committee desires to point out to the guardians that the scheme they are working in conjunction with Mr. Hookham will leave a large number of underfed children without a meal. Some of the members of the Aston board were of opinion that the Act did not give them all the powers they desired, but both boards were convinced that they had done what they could. Up to the present the Birmingham board had only received 800 applications, whilst the education authorities estimated that 2600 children were underfed; but it was pointed out that some parents who were neglectful in the past have, under the threat of being sued for the necessary money, undertaken to feed their children. It would be very regrettable if the children suffered from misunderstandings between different organisations, but it is quite time that many parents should be forced to recognise their responsibilities.

Cottage Homes for Boys.

It appears, from a discussion which occurred at a recent meeting of the King's Norton board of guardians, that the system of cottage homes in the Birmingham district is

proving a distinct success. Apparently the majority of the boys sent to the homes do well in after life, and the statement of the chairman of the cottage homes committee that although they drew their children largely from the gutter not more than 1 per cent. ever came back to the workhouse is very encouraging. The cost of cottage homes is slightly in excess of the boarding-out system but the results on the whole appear to justify the expense.

Lightwoods Park and Warley Woods.

The scheme for the acquisition of Lightwoods Park and Warley Woods is still progressing, though not perhaps so quickly as its promoters could desire. A sum of £70,000 is required and of this £28,000 are still to be obtained. The staff of the University has contributed over £51, and of the total sum hitherto secured £40,000 have been given by 600 people. The question of a contribution from Birmingham has received preliminary consideration by the general purposes committee and there seems to be a possibility that a substantial contribution may be recommended on the principle of securing as many public recreation grounds as possible in the immediate neighbourhood. It has been pointed out, however, that as the woods are outside Birmingham and immediately contiguous to Smethwick and Oldbury it would be well that those places should lead the way with larger contributions than they have hitherto promised.

Jan. 23rd.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Hospital Sunday in Liverpool.

FINE weather favoured the thirty-sixth Hospital Sunday collection which took place in the Liverpool churches on Jan. 14th. It cannot be said that in previous years the elements had been propitious. "Hospital Sunday weather" was fast becoming a synonym for all that was most inclement and disagreeable. Despite this most auspicious circumstance the results are not calculated to give unqualified satisfaction. Whilst many churches have increased their collections the majority have fallen. The decline is most noticeable in the case of those places of worship which are attended by wealthy congregations. The two most striking instances are Sefton Park Presbyterian Church (where the collection showed a falling off of £90) and St. Nicholas's Church, Blundellsands (where there was a drop of £50). The decrease at the latter church is difficult to account for but the falling off at Sefton Park Presbyterian Church may very safely be attributed to the fact that the Rev. Dr. John Watson (Jan MacLaren) no longer occupies the pulpit there, and that no regular minister has yet been appointed. The first place is again accorded to Ullet-road Unitarian Church, where the receipts showed a considerable increase over last year—£610 as against £552.

The West Kirby Appeal Case.

In the Court of Appeal on Jan. 23rd, before Lords Justices Vaughan Williams and Stirling, the hearing of the appeal of Dr. A. Bicknell of West Kirby against a judgment in favour of the plaintiff Hobson entered at the trial at the Liverpool assizes in May last was concluded. It will be remembered that the jury found that the defendant was wrong and guilty of negligence in his original diagnosis of the disease from which the plaintiff was suffering but that he afterwards acted with all care, and they awarded the plaintiff £70 for loss of wages and "tips" at the Golf Club. Lord Justice Vaughan Williams, in giving judgment, said that the question which the court had to decide was whether the defendant was negligent in the diagnosis which he made when he was called in to treat the plaintiff; and, secondly, whether the result that followed—that was to say, the dismissal of the plaintiff from his employment at the club—was brought about or caused by such a negligent diagnosis. The jury found that the defendant was negligent inasmuch as he accepted the diagnosis of Dr. Moss (who first examined the plaintiff) without sufficient examination but that subsequently he used all reasonable care. There was, in his lordship's opinion, a manifest difficulty in reconciling this finding with the verdict against the weight of evidence he should not have been inclined to interfere but

the question was whether the damages followed from the negligence. It was clearly shown that the plaintiff was dismissed as the result of a subsequent re-examination and it therefore was only possible to support the finding as to damages on the assumption of negligence subsequent to the first diagnosis, but there was an express finding of the jury that the defendant subsequently used all reasonable care and that being so it could not be said that the damages followed from negligence. For those reasons there must be judgment for Dr. Bicknell, the defendant. Lord Justice Stirling concurred and the appeal was allowed and judgment entered for the defendant, with the general costs of the trial, the plaintiff to have the costs of the issue on which he succeeded. Dr. Bicknell is to be congratulated on the result of the appeal.

Insanitary Swearing-in: a Medical Officer of Health's Objection at the Birkenhead Police Court.

Dr. R. Sydney Marsden, the medical officer of health of Birkenhead, giving evidence at the Birkenhead police court on Jan. 19th in a "bad meat" case, objected to the dirty condition of the Bible which was offered to him for swearing-in purposes. He respectfully suggested that it was time the magistrates should order a new Bible to be provided. The book was not in a sanitary condition and witnesses should not be asked to kiss it. As medical officer of health he thought it his duty to call attention to it. The deputy town clerk facetiously remarked that Dr. Marsden had better serve a notice on the magistrate to abate the nuisance. On being asked if he wished to have the book condemned Dr. Marsden, holding it up between his finger and thumb, remarked that he certainly should like an order for its destruction. The chairman said the matter would be attended to.

Small-pox in Liverpool: Russian Emigrants Isolated.

At the weekly meeting of the health committee Dr. E. W. Hope (medical officer of health) reported that there were 758 cases in hospital, including two cases of small-pox—Russian emigrants en route to America and now in the port sanitary hospital.
Jan. 25rd.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

School Influence in the Spread of Diphtheria.

At the meeting of the West of England and South Wales branch of the Incorporated Society of Medical Officers of Health held at Chepstow on Jan. 19th the President of the branch (Dr. Francis T. Bond) gave an account of the successful action which he recently took in connexion with an epidemic of diphtheria in the Thornbury rural district of Gloucestershire. For some months cases of the disease were regularly occurring among school children in one portion of the district until it appeared that some decided steps must be taken to put an end to the outbreak. As the centre of infection was apparently the public elementary school material was taken from the throat and nose of each of the 246 children who attended the school. Upon bacteriological examination it was found that Klebs-Loëffer bacilli were present in 65 per cent. of the children examined, the bacilli being found in the nasal specimens to double the extent of that in specimens taken from the throat. The school was kept open and for three weeks the throats and noses of all the children in the school were sprayed with a solution of carbolic acid and no further cases of the disease have been reported. The spraying and the swabbing were carried out by a local practitioner at the cost mainly of the rural district council and it is of interest to learn that when the education committee of the county council was asked to pay for the services thus rendered it replied that it had no authority to spend money in this way. Dr. Bond endeavoured to ascertain from the Local Government Board whether the local sanitary authority could properly pay for what he described as the "disinfection" of diphtheria throats. The Board replied that the authority had no express power to spend money for this purpose but it would be for the district auditor to say whether the payments were illegal.

Suggested Amendment of the Rules of the Central Midwives Board.

At the same meeting of the society Dr. J. Middleton Martin suggested some amendments to the rules of the

Central Midwives Board with special reference to those regulating the practice of midwives. He considered it inadvisable that women ignorant of their use should be obliged to carry catheters, appliances for giving injections, &c., for to some women the obligation to carry them implied that the appliances *must* be used. The rule which requires personal disinfection of the midwife after attendance upon a case of puerperal fever should be made more imperative and should be so worded as to make it clear that steam disinfection is really necessary. The rule which insists that a midwife shall not leave her patient after the commencement of the second stage Dr. Martin thinks is unfortunately expressed because many midwives do not know the meaning of such terms as presentation, second stage, &c. The rule which gives a qualified assent to the making of an internal examination by midwives he condemned and thought that they should be prohibited from making such examinations until after their methods of practice had been personally watched. As midwives in some districts only attend half a dozen or so of cases in a year it seemed desirable that the supervising authority should have discretion in enforcing the rule which prohibits the midwife laying out the dead, and some hardship might be entailed if she were not allowed to perform this office in the event of the death of either the patient or the baby. These were the most important amendments suggested and in the course of discussion Dr. A. G. Lawrence pointed out that it was really necessary to differentiate between rules for the trained and untrained midwives, for much harm would be done if weapons were put into the hands of untrained nurses with the use of which they were not familiar. He expressed the opinion, as a general practitioner of 45 years' standing, that no untrained midwife could tell a presentation or knew the meaning of the different stages of labour.

Eastern Dispensary, Bath.

The annual meeting of the subscribers to this institution was held on Jan. 18th under the presidency of the Mayor. The medical report stated that 3656 patients had been treated during the year. The financial statement showed that the year closed with an unfavourable balance of £46.

Bristol Medical Dramatic Club.

The Bristol Medical Dramatic Club will give performances of the *Pickpocket* on Feb. 13th and four following days. The proceeds will be devoted towards the purchase of an athletic ground for the Bristol Medical Clubs Union.
Jan. 25rd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Morison Lectures at the Royal College of Physicians of Edinburgh.

THESE lectures are to be delivered in the College Hall on Wednesday, Jan. 24th, Friday, Jan. 26th, and Monday, Jan. 29th. The lecturer is Dr. W. Ford Robertson, superintendent of the Scottish Asylums Laboratory, and his theme is the Pathology of General Paralysis of the Insane. Lecture I. deals with "the prevalence and recent increase of general paralysis, current opinions regarding its causation, recent investigations in the Laboratory of the Scottish Asylums and Edinburgh Royal Asylum, bacteriological, histological and experimental researches; the detection of diphtheroid bacilli in the blood, walls of the cerebral vessels, cerebro-spinal fluid, and urine." Lecture II. includes "the experimental study of the action of the living blood upon pure cultures of diphtheroid bacilli isolated from cases of general paralysis and tabes dorsalis; how the results obtained have led to the demonstration of the infective nature of these diseases; search for a specific reaction of the blood in cases of general paralysis." The concluding lecture is confined to "the etiology and pathogenesis of general paralysis and tabes dorsalis. How are these diseases to be combated?"

The Parliamentary Representation of the Universities of Edinburgh and St. Andrews.

The voting papers for the election of a member to represent these Universities in the new Parliament have just been issued. The papers have to be in the hands of the registrar duly signed and witnessed by Feb. 8th. The names of the candidates and the sides of politics to which they

adhere are matters of common knowledge to readers of the daily newspapers.

Women Graduates and the Election of University Parliamentary Representatives.

An interesting point has just arisen in connexion with the election of Parliamentary representatives for the Scottish universities. The point is that women graduates are on the registers of the general councils of the universities and they claim that voting papers should be sent to them. They hold that there is nothing in the Act regulating the universities' elections which distinctly debars them from the privilege and that the duty of the registrars is "to forward to each voter, to his address as entered in the register of the general council of the University, who shall appear from said address to be resident within the United Kingdom and the Channel Islands," the necessary voting paper. The registrars have not taken this view and they are said to be guided by high legal opinion on the matter. The statute dealing with the elections says that "no person subject to any legal incapacity shall be entitled to vote at any election or exercise any other privilege as a member of the general council of any university," and from this the registrars maintain that the women graduates come under the category of those who are "subject to legal incapacity." A meeting of women graduates of the Scottish universities to consider the position has been called for the 27th inst. to be held in Edinburgh. The matter is meanwhile in the hands of a provisional committee of which Miss C. Macmillan is secretary. There is now a large number of graduates in arts and medicine interested in this question and more will doubtless be heard of it.

Royal Medical Society, Edinburgh.

A meeting of this society was held on Jan. 19th, Dr. A. W. Neill being in the chair, when Dr. D. Newman of Glasgow gave a demonstration on Cystoscopy. The lecturer first showed how in cases of disease of the kidney and bladder differential diagnosis is frequently impossible without the aid of the cystoscope, and thereafter, by means of a special apparatus for the purpose, he showed a number of interesting pictures of the appearances of the bladder in health and disease. Dr. Newman, by an ingenious device, demonstrated the appearance produced by normal urine, pus, blood, &c., passing into the bladder from the ureter; and he explained the mechanism of the cystoscope which he uses and which shows a number of improvements on the ordinary instrument, notably a double eye-piece, with the aid of which Dr. Newman had succeeded in obtaining excellent drawings of bladder conditions. On the motion of Dr. Chambers, seconded by Dr. Wells, the lecturer was unanimously accorded a very hearty vote of thanks for his most interesting demonstration. The presidents of the society have issued invitations to their annual dinner which is to be held on Wednesday, Feb. 7th. Professor T. Olifford Allbutt is to be the guest of the evening.

Scottish Branch of Queen Victoria's Jubilee Institute for Nurses.

The seventeenth annual report of this admirable and useful institution shows continued success. Owing to the resignation of the superintendent, Miss Wade, on account of her health, Miss Cowper has been promoted to fill her post. During the year with which the report deals the council was responsible for 41 nurses and probationers. There are now 268 Queen's nurses in Scotland working under 174 affiliated branches; and the last report of the council of the institute gives the number in England as 672 in 335 branches, in Wales 100 in 75 branches, and in Ireland 94 in 81 branches. As the report says, the fact that the nurses of the institute are to be found in districts ranging from a crowded manufacturing town to a sparsely peopled Highland estate "is an encouraging evidence of the adaptability of the system of nursing recommended by the institute."

The Eyesight of School Children.

The London County Council led the way in the matter of making a systematic examination of the eyesight of school children and Glasgow and Govan school boards have been following its example. In an interesting paper read before the Royal Philosophical Society Dr. W. B. Inglis Pollock summarised some of the results obtained by a routine examination of the eyes of scholars in three schools under the Govan board. In one school there were 8.2 per cent. with

defective vision and 21.6 with fair vision; in another the corresponding figures were 9.2 and 12.7 per cent.; and in the third they were 22.2 and 30.3 per cent. Taking the three schools together, the defective percentage remained very constant for the young children, and then gradually fell during the ages of ten to 14 years, when it increased very rapidly. Dr. Pollock pointed out that 12 per cent. of all scholars had hypermetropic astigmatism, which meant that by the age of 35 years all such individuals would need to use glasses for near work. Many workmen of that age stated that they would be thrown out of employment if they put on glasses but Dr. Pollock thought this was a mistaken policy on the part of the employers, as in engineering works men would be better protected with glasses from "fires" and chips of steel, and thus companies would save the money paid in compensation for the time men were off work being treated for ulcers and wounds of the eye. As matters now stand, however, it was advisable that hypermetropic boys should be warned not to enter upon trades where they were likely to lose their employment at an early age, and the only way to detect such cases was by a systematic examination of all boys on leaving school. Among 3183 children 71 had squints. The percentage of myopia began as 1.7 at the age of five years, rose steadily to 8.4 at 13 years of age, and thereafter rose with a bound to 25 at 18 years of age. These statistics need no comment.

Jan. 23rd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Election of a Direct Representative for Ireland on the General Medical Council.

SINCE Jan. 22nd the voting papers for the above election have been gradually distributed among the 2800 electors. The count is fixed to take place on Saturday next, Feb. 3rd, and there is considerable interest as to the result of the contest which is taking place between Sir William Thomson, the sitting member, and Dr. Leonard Kidd of Enniskillen. It is well known that many hundreds of the country medical practitioners of Ireland are in favour of supporting a member of their own body and it is therefore by no means certain that Sir William Thomson may not be displaced, although his ten years of good work on the Council are appreciated by all classes of the profession in Ireland. A second motive will also dictate votes in favour of Dr. Kidd. It happens that all the other Irish members of the Council—Sir John W. Moore, Sir Christopher J. Nixon, Sir Thomas Myles, James Little, Dr. Edward H. Bennett, and Lieutenant-Colonel F. G. Adaye-Curran—are residents in Dublin, and there is a feeling abroad that the rest of Ireland would be better represented by someone not living in the capital.

Public Health of Dublin.

The last meeting of the public health committee of the corporation took place on Jan. 17th when Sir Charles A. Cameron reported that the death-rate was very low during the previous two weeks as compared with the corresponding period of the last ten years. The general death-rate was 23.3 as against an average of 33.7 per 1000. The zymotic death-rate was 0.9 per 1000 as against 2.9 for the corresponding period of the previous ten years. Of the total number of deaths no less than 52, or nearly one-third, were among children under five years of age and of these a majority had not reached one year. The last meeting of the governors of Cork-street Fever Hospital took place on Jan. 18th, when the medical superintendent reported that a large number of severe cases of pneumonia and erysipelas were admitted during December, also cases of diphtheria and scarlet fever, while the number of cases of enteric fever had decreased. With reference to a proposed sanatorium for consumption at a meeting of the corporation held on Jan. 22nd Sir Charles Cameron received the permission of the public health committee to convene a meeting of the representatives of the urban and district councils of the county of Dublin to consider the subject of the establishment of a sanatorium for the treatment of consumption.

Death of Dr. Henry S. Purdon.

I regret to announce the death on Jan. 21st, after a painful and tedious illness, of Dr. H. S. Purdon of Belfast at the age of 62 years. The son of a former well-known medical

practitioner in Belfast—Dr. C. D. Purdon—Dr. H. S. Pardon studied in Belfast, Dublin, and Glasgow, where he graduated M.D. in 1865, and in the same year he became L.R.C.P. of Edinburgh, having also in the previous year become a Licentiate of the Royal College of Surgeons in Ireland. After commencing practice in Belfast, he became physician to the old Royal Hospital, a position which he resigned on being appointed certifying factory surgeon for Belfast in succession to his father—a lucrative post. He was also physician to the Belfast Charitable Society and to the Forster Green Hospital for Consumption and Diseases of the Chest. He opened a dispensary for skin diseases in 1865, which subsequently, owing to the munificence of the late Mr. Edward Benn of Belfast, developed into the Skin Hospital with 18 beds. For many years he was the leading Ulster medical authority on cutaneous diseases and wrote many papers on the subject and was also for a time editor of a "Journal of Cutaneous Medicine." Dr. Pardon was fond of music and antiquities and at one time was a member of the choir of St. George's Church, Belfast. He was a genial and kind hearted man with many friends among the profession and the public. He leaves a widow, three sons (two of whom are medical men), and five daughters.

Longford County Infirmary.

An unfortunate state of affairs has arisen at Longford County Infirmary through the existence of serious differences of opinion between the medical officer and the committee of management. In his monthly report presented at a meeting of the committee held on Jan. 17th, Mr. Nathaniel Mayne, the medical officer, complained that certain extra duties recently assigned to him would require him to be in constant attendance at the infirmary and would thereby preclude him from undertaking private practice. A published report of the events of this meeting shows that the committee in sanctioning or refusing the supply of medical and surgical appliances takes the advice not of Mr. Mayne but of the matron and the registrar. In a letter published in the *Irish Times* of Jan. 19th Mr. Mayne makes a very reasonable reply to a charge made against him of admitting patients without tickets, his explanation being that the applicants for admission were too ill to be sent away.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Professional Secrecy and the Examination of Prostitutes.

At the meeting of the Society of Legal Medicine held on Jan. 8th M. Batte said that one argument employed by those who objected to the State examination of prostitutes was that the medical men whose duty it was to carry out the examinations could not legally fulfil such duties. They could not, because in sending in to the authorities the diagnosis of the diseases which they found in the women who came to them they had to violate their oath of professional secrecy. M. Batte argued that no violation existed. The medical men who are attached to the particular department in question of the State are not, so far as these duties go, practising medical men. They act simply as experts and as delegates of the prefect of police just in the same way as do inspectors of wet nurses. The woman who comes to any one of them does not confide in him, she knows that she goes to be examined and why she does so. This being so there is no secrecy about the matter and, consequently, no violation of secrecy.

Bilateral Tarsectomy for Double Club Foot.

At the meeting of the Surgical Society held on Jan. 8th M. Broca read for M. Jeanbrau a paper dealing with the case of a young man, aged 23 years, who suffered from double club foot due to paralysis. M. Jeanbrau had obtained a good result by performing an extensive tarsectomy on either side, several bones being removed. M. Broca thought that a good result might always be looked for in such cases, at least in the adult. The case reported by M. Jeanbrau was, however, a striking example of the good results to be obtained by putting up the foot after tarsectomy in an immobile apparatus after having previously placed it in good position. The apparatus was not removed until the foot had become fixed in the new position. In the case in question one foot had been immobilised and the other had been treated by gentle movements

and early massage. A much better result was obtained in the immobilised foot than in the other one.

Administration of Drugs by Night.

At a recent meeting of the Therapeutical Society M. René Laufer drew attention to a fault of omission which is very common in the use of drugs. The general custom is to give drugs by day, generally at meal times, and no notice is taken of the fact that it would be quite possible to vary the time of giving them with good results. A large number of pathological conditions occur at night, such as asthma and epileptic fits; others are increased at night, such as syphilitic pains. Others which go on steadily all the 24 hours are only treated during the day, that is to say, during half the time of their existence. To this pathology of the night it is only reasonable to oppose a therapy of the night. As in the case of certain fevers quinine is not given at meal times but at certain definite periods before the access of the fever, so in pathological conditions the administration of the selected medicine ought to be given at not too long a period before the manifestation of the attack. M. Laufer related five cases in support of his argument, one being a case of asthma where iodide given at night entirely prevented the attack although the same dose given by day had no effect in preventing the attacks. M. Laufer has used the same method of administration of drugs in certain cases of neuralgia and bronchitis. He noted that when a drug is given at night its activity is markedly increased on account of the rapidity of absorption. In practice he finds that the best method of administering drugs at night is to divide them into two doses, one to be given on going to bed and the other in the middle of the night.

Cervical Actinomycosis.

At the meeting of the Society of Dermatology and Syphilography held on Jan. 11th M. Pantrier showed a patient who was an agriculturist and who had been in the habit of chewing ears of grasses. In September, 1903, he presented a tumour at the angle of the jaw on the left side in which were found the characteristic yellow granules of actinomycosis. To remove it a portion of the angle of the jaw had to be taken away as well. Four months later cutaneous lesions began to develop in the neck and here also were found actinomycotic granules. Treatment by iodides had not so far brought about any improvement.

Experiments on Syphilis.

Professor Neisser of Breslau, together with his assistants, Dr. Baermann and Dr. Halberstädter, has visited Batavia, in the island of Java, for the purpose of studying the inoculation of apes and monkeys with syphilis and a lengthy report of his work has been published by him in the *Deutsche Medizinische Wochenschrift*. Orang outangs, gibbons, and macaques were used for these experiments, the virus being taken from hospital patients. It was found that the incubation period varied from 15 to 65 days, in the majority of cases being from 26 to 45 days. The virus was inoculated into scarifications. The primary chancre which subsequently appeared varied considerably in superficial extent and in depth but, as a rule, was very like human chancre. Virus taken from recent chancres produced more characteristic symptoms than other virus, that from chancre in the course of healing did not produce any positive results, whilst the effects of those from primary adenitis, condylomata, and plaques muqueuses were marked. Material taken from a gummata produced chancre in two out of three cases and it was remarkable that the incubation period in these cases was exceptionally long. Inoculation of human blood and blood serum proved negative and of the organs only the spleen, the glands, the bone marrow, and the testicles gave positive results. Professor Neisser says that he is not sure whether there is a difference in the virulence of the infective material according as it is taken from the human subject, from the orang-outang, or from lower monkeys, but apparently the virus became stronger by passage through different animals. It is remarkable that the higher species of monkeys are more liable to syphilis than the lower and that in the higher species the virus may be successfully inoculated in every region of the body, while in the lower species the inoculation takes effect only in the eyebrows and in the

adhere are matters of common knowledge to readers of the daily newspapers.

Women Graduates and the Election of University Parliamentary Representatives.

An interesting point has just arisen in connexion with the election of Parliamentary representatives for the Scottish universities. The point is that women graduates are on the registers of the general councils of the universities and they claim that voting papers should be sent to them. They hold that there is nothing in the Act regulating the universities' elections which distinctly debar them from the privilege and that the duty of the registrars is "to forward to each voter, to his address as entered in the register of the general council of the University, who shall appear from said address to be resident within the United Kingdom and the Channel Islands," the necessary voting paper. The registrars have not taken this view and they are said to be guided by high legal opinion on the matter. The statute dealing with the elections says that "no person subject to any legal incapacity shall be entitled to vote at any election or exercise any other privilege as a member of the general council of any university," and from this the registrars maintain that the women graduates come under the category of those who are "subject to legal incapacity." A meeting of women graduates of the Scottish universities to consider the position has been called for the 27th inst. to be held in Edinburgh. The matter is meanwhile in the hands of a provisional committee of which Miss C. Macmillan is secretary. There is now a large number of graduates in arts and medicine interested in this question and more will doubtless be heard of it.

Royal Medical Society, Edinburgh.

A meeting of this society was held on Jan. 19th, Dr. A. W. Neill being in the chair, when Dr. D. Newman of Glasgow gave a demonstration on Oystoscopy. The lecturer first showed how in cases of disease of the kidney and bladder differential diagnosis is frequently impossible without the aid of the cystoscope, and thereafter, by means of a special apparatus for the purpose, he showed a number of interesting pictures of the appearances of the bladder in health and disease. Dr. Newman, by an ingenious device, demonstrated the appearance produced by normal urine, pus, blood, &c., passing into the bladder from the ureter; and he explained the mechanism of the cystoscope which he uses and which shows a number of improvements on the ordinary instrument, notably a double eye-piece, with the aid of which Dr. Newman had succeeded in obtaining excellent drawings of bladder conditions. On the motion of Dr. Chambers, seconded by Dr. Wells, the lecturer was unanimously accorded a very hearty vote of thanks for his most interesting demonstration.—The presidents of the society have issued invitations to their annual dinner which is to be held on Wednesday, Feb. 7th. Professor T. Olifford Allbutt is to be the guest of the evening.

Scottish Branch of Queen Victoria's Jubilee Institute for Nurses.

The seventeenth annual report of this admirable and useful institution shows continued success. Owing to the resignation of the superintendent, Miss Wade, on account of her health, Miss Cowper has been promoted to fill her post. During the year with which the report deals the council was responsible for 41 nurses and probationers. There are now 268 Queen's nurses in Scotland working under 174 affiliated branches; and the last report of the council of the institute gives the number in England as 672 in 335 branches, in Wales 100 in 75 branches, and in Ireland 94 in 81 branches. As the report says, the fact that the nurses of the institute are to be found in districts ranging from a crowded manufacturing town to a sparsely peopled Highland estate "is an encouraging evidence of the adaptability of the system of nursing recommended by the institute."

The Eyesight of School Children.

The London County Council led the way in the matter of making a systematic examination of the eyesight of school children and Glasgow and Govan school boards have been following its example. In an interesting paper read before the Royal Philosophical Society Dr. W. B. Ingills Pollock summarised some of the results obtained by a routine examination of the eyes of scholars in three schools under the Govan board. In one school there were 8.2 per cent. with

defective vision and 21.6 with fair vision; in another the corresponding figures were 9.2 and 12.7 per cent.; and in the third they were 22.2 and 30.3 per cent. Taking the three schools together, the defective percentage remained very constant for the young children, and then gradually fell during the ages of ten to 14 years, when it increased very rapidly. Dr. Pollock pointed out that 12 per cent. of all scholars had hypermetropic astigmatism, which meant that by the age of 35 years all such individuals would need to use glasses for near work. Many workmen of that age stated that they would be thrown out of employment if they put on glasses but Dr. Pollock thought this was a mistaken policy on the part of the employers, as in engineering works men would be better protected with glasses from "fires" and chips of steel, and thus companies would save the money paid in compensation for the time men were off work being treated for ulcers and wounds of the eye. As matters now stand, however, it was advisable that hypermetropic boys should be warned not to enter upon trades where they were likely to lose their employment at an early age, and the only way to detect such cases was by a systematic examination of all boys on leaving school. Among 3183 children 71 had squints. The percentage of myopia began as 1.7 at the age of five years, rose steadily to 8.4 at 13 years of age, and thereafter rose with a bound to 25 at 18 years of age. These statistics need no comment.

Experiments on Syphilis.

Professor Neisser of Breslau, together with his assistants, Dr. Baermann and Dr. Halberstädter, has visited Batavia, in the island of Java, for the purpose of studying the inoculation of apes and monkeys with syphilis and a lengthy report of his work has been published by him in the *Deutsche Medizinische Wochenschrift*. Orang outangs, gibbons, and macaques were used for these experiments, the virus being taken from hospital patients. It was found that the incubation period varied from 15 to 65 days, in the majority of cases being from 26 to 45 days. The virus was inoculated into scarifications. The primary chancre which subsequently appeared varied considerably in superficial extent and in depth but, as a rule, was very like human chancre. Virus taken from recent chancres produced more characteristic symptoms than other virus, that from chancre in the course of healing did not produce any positive results, whilst the effects of those from primary adenitis, condylomata, and plaques muqueuses were marked. Material taken from a gumma produced chancre in two out of three cases and it was remarkable that the incubation period in these cases was exceptionally long. Inoculation of human blood and blood serum proved negative and of the organs only the spleen, the glands, the bone marrow, and the testicles gave positive results. Professor Neisser says that he is not sure whether there is a difference in the virulence of the infective material according as it is taken from the human subject, from the orang-outang, or from lower monkeys, but apparently the virus became stronger by passage through different animals. It is remarkable that the higher species of monkeys are more liable to syphilis than the lower and that in the higher species the virus may be successfully inoculated in every region of the body, while in the lower species the inoculation takes effect only in the eyebrows and in the

genitals. This local immunity of macaques could not be overcome either by inserting the virus into artificial wounds of the skin or by combining the syphilitic virus with vaccine. With regard to the course of the disease it was found that in the lower monkeys the animal's general state was not at all altered, whilst in orang-outangs dyspepsia, dysentery, and debility showed themselves. Primary adenitis was observed only in the anthropoid apes; in the lower species glandular changes were not perceptible until the necropsy was made. As to the secondary symptoms, papular exanthemata were observed in some of the gibbons on the face, on the abdominal and gluteal regions, on the hands, and on the mucous membranes. In the orang-outang no secondary symptoms developed; in the lower monkeys there were local eruptions of annular and serpiginous form in the neighbourhood of the primary chancre. Professor Neisser further states that he was unable to produce syphilis by subcutaneous injection, either in gibbons or orang-outangs or lower monkeys, nor was immunity obtained by these injections. The virus is therefore obviously destroyed in the subcutaneous tissue of a healthy animal, but possibly subcutaneous injections of the virus into a syphilitic animal may produce immunising antitoxins. The experiments are, however, not yet finished. Injections into the blood-vessels and into the peritoneal cavity were also unsuccessful. It was found that the virus lost its efficacy within six hours; material taken from a dead body after 18 hours was inert and attempts to preserve it by means of glycerine, paraffin, and other substances were unsuccessful. Experiments were also carried out for the purpose of ascertaining whether the development of syphilis could be cut short by excision of the place of the injection at varying intervals previously to the appearance of the chancre, the result being that the chancre developed in eight out of 14 cases. In two cases there was no formation of chancre, while in the remainder either the appearances were uncertain or the animal died at an early stage. It is remarkable that in one case where the part was excised eight hours after the infection chancre nevertheless developed. Other experiments were made for the purpose of determining the time within which syphilis may become general but were not yet finished. The administration of mercurials did not prevent the eruption of general syphilis. Professor Neisser finally discusses the possibility of immunisation against syphilis and the results of bacteriological examinations. He stated that the spirochæte pallida, recently alleged to be the cause of syphilis, was probably in etiological connexion with the disease but that practically the presence or absence of the spirochæte did not prove anything either for or against the question of infectivity. Professor Neisser has returned to Germany but the research will be continued by his assistants who remain in Java.

A Model Institution for Infants.

On the occasion of the silver wedding of the German Emperor and Empress a series of benevolent institutions will be founded by public subscription. One that will certainly be received with approval by the medical profession is a model institution for infants. At a meeting of the committee under the presidency of Dr. Schönstedt, late Minister of Justice, when among others Dr. Heubner, professor of children's diseases in the University of Berlin, was present, some particulars were given about the proposed institution. The "infants' home" is to be erected at Charlottenburg, a suburb of Berlin, on a site presented to the Empress for this purpose by the municipal authorities of that town. The institution will include several departments. In the first department pregnant women will be received three months previously to their confinement and after it they will stay there for a fortnight. The children must be fed by the mother and they are therefore transferred to another department termed the "mothers' home," where they stay for three months. For children who have to be fed artificially on account of their mothers being unable to suckle them a third department will be provided, where, moreover, children born outside the institution are to be received. A fourth department is destined for sick infants. In connexion with the institution there will be a large dispensary (*Fürsorgestelle*), which will undertake the after-care of mothers and children who have left the home and where mothers and pregnant women may obtain advice and will be provided with food. Large chemical and bacteriological laboratories and a model cow-house are to be

erected, and in addition to the medical and nursing staff a training school for special nurses for children will be attached to the institution.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

Measles in Milan.

THE health conditions of the Lombard capital have a more than domestic importance. Representatives of every nationality in Europe pass through Milan or pause on the wing within its gates on their way to or from the great Italian centres or to or from Egypt and the Far East. Short as is their sojourn, it is, as experience has shown, quite long enough to expose them to the risks of infectious disease which in one form or another is never quite absent from a city the water-supply of which is still drawn from subsoil or other sources leaving much to be desired. In the day now passing it is measles which is the most prevalent in the Milanese environs and central quarters—measles not only of a pronounced infective type but prone to assume complications mostly broncho-pneumonic in character. Starting from the communal villages, where the returns for December give 212 cases at Boffalora Ticino, 143 at Abbiategrasso, 43 at Assago, 100 at Magnago, 45 at Turbigo, and 40 at Canegrate, it has invaded the city itself till the sojourner within it can hardly venture with safety into its railway station, or its galleries, or its houses of public entertainment, or even its tramcars and omnibuses. It is but just to say, however, that the sanitary authorities are fully alive to the danger besetting the city and are carrying out the most stringent precautions by way of circumscribing its "sphere of influence." All cases, for instance, declaring themselves in schools, asylums, and industrial establishments employing juvenile labour, are at once isolated and subjected to appropriate treatment, and so far with a success which implies intelligent co-operation on the part of the heads of the said establishments or institutions. As a great *entrepôt* of foreign travel Milan owes it to the outside world from which she derives so much solid gain to follow up the sanitary measures which she is now putting in practice with a still wider and more thorough-going programme which will include improvement of her water-supply and the sweeping away of her "fever preserves."

The New Surgical Clinique at Pisa.

The ancient University of Gallia and Cesalpino, of Vaccaro and Puccinotti, has been holding high festival on the occasion of the opening of its "Nuova Clinica Chirurgica." This adjunct to its teaching equipment, long required but inevitably postponed, has at length been carried to completion, mainly through the energy and personal influence of Dr. Antonio Ceci, professor of surgery in the Pisan School and respected throughout Italy as one of her best teachers and operators in that department of medicine. Private liberality on his own part and on that of his friends, reinforced by munificent contributions from the King and the Government, has been rewarded by the realisation of its object in the fine, commodious, and eminently serviceable structure in which the Pisan medical student will now perfect himself in surgery under conditions second to none in any other Italian seat of learning. The inaugural ceremony, in which the Senatus Academicus of Pisa and representatives of all the other sister universities took part, was graced by a peculiarly felicitous address from the rector, Professor David Sapino, who took occasion to review the successive stages through which surgical and medical practice and teaching had passed within the Pisan School itself—from the days when in 1543 there were two necropsies within the twelvemonth, graciously conceded or authorised by the Grand Duke, to the present time when every year witnesses 300 necropsies at least; while no farther back than 1870 the number of operations averaged 70 per annum and now there are as many as 500 within the same period. After the rector came the professor of clinical medicine, Dr. Queirolo, who, speaking in the name of the Minister of Public Instruction, evoked repeated salutes of applause in his enumeration of the services of Professor Ceci and of the architect, Professor Caselli. He was followed by these two latter who, each in his own department, drew an impressive picture of the difficulties to be surmounted before the result so universally admired could be achieved.

In the evening Professor Ceci entertained at the Hôtel Nettuno a large number of guests, including the local medical faculty and the delegates from the sister schools and again the oratory was of that brilliant character traditional in the academic Saturnalia of Italy.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Hypertrichosis graviditatis.

A NOVEL symptom of pregnancy, or at least one which has received little attention, has been noted by Dr. Halban and he made it the subject of a paper which he read at a recent meeting of the Vienna Gynecological Society. He had noticed for several years that brunettes who in Austria very often show rudiments of a moustache developed during pregnancy a fairly visible masculine type of hair on the upper lip. Systematic observation has convinced Dr. Halban that pregnancy stimulated excessive growth of hair not only on the face but also on all other parts of the body. In particular the lanugo of the abdomen and the extremities was very often influenced by pregnancy, but Dr. Halban was not prepared to state whether the hair of the axilla or pubes was affected. The increased growth might be noticed from the second month of pregnancy and continued till the end of normal gestation or, to speak more exactly, till the expulsion of the placenta, when these hairs had a tendency to fall out again, as could be seen very clearly on the mammae and on the linea alba, where hair of from one to two inches in length might disappear a few days after delivery. Dr. Halban thought that certain active principles connected with the placenta or with the epithelium of the chorion were responsible for the changes by producing hyperæmia and thus better nutrition of glandular organs, as is already known for the mammae. This hypothesis, which was well supported by many experiments on rabbits and dogs, would give a good explanation for the increased growth of the hair seen on the foetus from the sixth month, and would be consistent also with another fact noticed by a number of obstetricians—namely, that many females who become pregnant at a time when the growth of their bones has not yet been arrested grow more rapidly during pregnancy than either before or after it. The women became aware of this by finding that the skirts which they had been wearing for six months required to be lengthened.

A Case of Congenital Dilatation of the Colon.

Professor Escherich recently showed at a meeting of the Pediatric Society some specimens taken from a child, three and a half years old, who had been suffering since birth from a very rare form of intestinal disease called Hirschsprung's disease after the name of the observer who first described it. The birth was normal but the child's abdomen was enormous. An enema which was immediately administered succeeded in bringing away three-quarters of a pint of meconium and after a few hours the infant vomited masses of meconium. The abdomen diminished a little but it remained always unusually large, with a well-marked caput medusæ (dilatation of the umbilical veins). Evacuations of the bowels had to be obtained by enemata, as spontaneous motions never occurred. Therapeutic measures in the form of faradic irritation of the abdominal muscles, massage, and passive exercises intended to strengthen the muscular walls were tried but without any appreciable effect. When the child was weaned the condition was still worse. An operation was ultimately performed, the ampulla recti, with a part of the colon, being amputated but the child died soon afterwards from exhaustion. The post-mortem examination revealed an enormous dilatation of the cæcum, the transverse colon, and the sigmoid flexure, whilst the muscular coats of the parts lying between the distended sections were greatly hypertrophied, the increase taking place chiefly in the stratum of circular muscles. The stomach measured only two and three quarter inches in its longest diameter. There are only 50 cases of such a condition on record. It is mostly congenital; it may also be acquired very early in childhood and is usually fatal from auto-intoxication or exhaustion.

Sarcoma of the Mediastinum.

Dr. Sternberg showed on a recent occasion some of the viscera of a man who died half an hour after admission to

hospital and who presented extensive oedema of the upper half of the trunk and arms and cyanosis of the face. The necropsy explained the condition. A spindle-celled sarcoma occupied the whole anterior half of the mediastinum, had attacked both lungs, and was three inches in thickness on the frontal aspect of the heart. The pericardium had disappeared and the right auricle, the right ventricle, and part of the left ventricle were in contact with the diaphragm. The remainder of the heart was invaded by the heteroplastic mass and could not be detached from it. The cavities of the heart were exceedingly narrow and the muscle was very friable. All three coats of the aorta and the pulmonary artery were involved in the tumour and from the ostium of the superior vena cava there protruded a long polypoid mass into the lumen of the auricle. The vein itself was nearly blocked by the tumour, only a very narrow lumen being left. Numerous secondary deposits were found in the lungs and the liver. The interest of the case centred in the abnormal mechanical condition involving the heart. It was hardly possible to surmise in what manner the systole and diastole of the heart took place, as nearly the whole of the muscular wall was fixed by unyielding tissue and as there was no pericardial membrane left. Another remarkable fact was the absence of deposits within the bones or in the lower parts of the body, although the vessels were mere canals within the foreign mass.

Spirochæta Pallida in a Primary Chancre and in the Liver.

Dr. Volk, who is endeavouring to prove the existence of the supposed micro-organism of syphilis in all manifestations of that disease, has prepared several films from an excised chancre in which there could be seen several spirochætes within the fibres of the connective tissue and between the cells of the deep portions of the Malpighian layer. They were stained by Levaditi's method, which has the effect of rendering the micro-organism black by a precipitate of silver. Out of five slides only one was useful, illustrating the difficulty of looking for the faintly coloured organism. In the liver they were found much more frequently. The liver was that of an infant, aged six months, who had died from intestinal catarrh, and in whom syphilitic symptoms were manifest at birth, but subsided quickly after treatment with iodine. In the blood of the patient from whom the chancre had been excised the spirochæte had been found on several occasions but could not be demonstrated as the films were spoiled.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

A New Hospital for New York City.

THE late Mr. Charles T. Yerkes in his will directed that a sum not to exceed \$800,000 is to be used for the purchase of a suitable site and the erection thereon of a hospital building in the Borough of the Bronx, a section in the northern part of the city now growing very rapidly and at present but poorly supplied with hospital facilities. The support and maintenance of the hospital are also provided for by the setting apart of an endowment fund of about \$5,000,000, the income of which is to be used for this purpose. The testator further directs that the institution shall be open to the public without regard to race, creed, or colour, and that those unable to pay shall be cared for free of all charge. According to the provisions of the will the necessary funds would not be liberated for this purpose until after the death of Mrs. Yerkes who is to receive the income of the residuary estate during her life but she is said to have expressed the intention, if legally possible, of beginning the work at once.

Obstetric Rareties.

From Bristol, Virginia, comes the remarkable story that a ten-year-old coloured girl of that town has just been delivered of a full-sized infant. To parallel this it is reported from Albany in New York State that a woman, aged 20 years, a short time ago gave birth to a child 116 days after having brought another infant into the world. The first labour was attended by a midwife but the medical man who was present at the second one states that both children are normal.

A New Army Hospital.

Congress has provided for the erection of a new Army General Hospital at Washington at a cost not to exceed

\$300,000 for the building. A site has already been selected and plans have been prepared and accepted.

Ambulances at Fires.

According to an arrangement which has been made with the larger hospitals of Philadelphia an ambulance will henceforth be present at all fires within the urban area. The city has been divided into suitable districts and each hospital is to respond to fire alarms occurring in its portion.

Football Accidents.

An interesting confirmation of the view that the current public disapprobation of the game of football as now played is not ill-founded is furnished by a recent publication in the *Boston Medical and Surgical Journal*. Dr. Edward H. Nichols and Dr. Homer B. Smith, the two surgeons upon whom devolves the care of the football squad of Harvard University, have summarised the result of their professional attendance on the players and arrive at conclusions quite in accord with the belief that the game involves risks of physical injury disproportionate to its value as an athletic exercise. A table is given showing the injuries received during the season extending from Sept. 12th to Nov. 25th, 1905, by the football squad, which represents a real playing strength of about 70 men. The list of important injuries reaches the total of 145. The injuries most often noted are cuts (requiring stitches), sprained ankle, cerebral concussion, and dislocation of the acromial end of the clavicle. These all occur ten or more times, the number of concussions, for example, being 19, and only two games were played in which an accident of this sort did not occur. A case of middle meningeal hæmorrhage, four fractures of the brim of the pelvis, and seven broken noses also figure in the table. The authors describe the general plan of treatment of the common injuries, which in some respects differs from that usually employed owing to the necessity of taking some chances in accordance with the imperative demands of the patients to be allowed to return to play at an earlier date than would be usual in ordinary practice. Considerable importance is attached to the fact that owing to the precautions taken to secure extreme personal cleanliness by insisting that only fresh towels should be used, the underclothing be changed frequently, &c., no infected wounds or skin infections occurred. As a result of their experience the authors reach the conclusion that the number, severity, and permanence of the injuries received in playing football are much greater than is generally credited or believed. The greater number of the injuries come in the "pile" and not in the open plays, although serious injuries also occur in the open. The number of injuries is inherent in the game itself and is not especially due to competition, as is shown by the fact that the proportion of injuries received in games and in practice is about the same. Most of the injuries are unavoidable and their percentage is incomparably greater in football than in any other of the major sports. The game does not develop the best type of men physically, because too great prominence is given to weight without any corresponding development of nervous energy. The percentage of injuries is too great for any mere sport and it is a question if a game requiring the constant attendance of two trained surgeons is played under desirable conditions.

Medical Men and Pharmacists.

The medical men and druggists of the State of Iowa are at variance and have been accusing each other of encroaching on their respective privileges. The mutual recriminations have reached such a point that the State government is to be appealed to, and each camp is circulating a petition for signatures which will later be presented in the form of a Bill before the legislature. The grievance of the medical men is that the druggists have made a practice of "counter prescribing," while the pharmacists allege that they have been driven to this usurpation of medical prerogative by the tendency of the physicians to furnish drugs to patients instead of writing prescriptions.

Urban Health Conditions.

New York city's death-rate for 1905 makes a very favourable showing as compared with previous years. In 1904 the mortality per 1000 was 20.01 but in 1905 it was reduced to 18.25, which is next to the lowest figure on record. The number of deaths from contagious disease is lower than ever before. In 1905 the births numbered 103,852, a gain of 4297 over the statistics of the previous year. The marriages

also were more numerous, for in 1905 42,667 were registered, as against 39,436 in 1904. The deaths were decreased almost exactly as much as the births increased, for the deaths in 1905 were 73,450, while for 1904 they were 78,060. In Chicago the death-rate has also been greatly reduced, and during one week in December it was only 12.80 per 1000, which is the lowest figure ever recorded in that city. For the entire year of 1905 it was less than 14 per 1000. The average duration of life in 1873 was 15 years, but now the average age of those dying is over 32 years. Philadelphia has been suffering from an epidemic of measles and in one week 201 cases of this disease and 152 of typhoid fever were reported.

Jan. 16th.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Mahomedan Pilgrim Traffic from Bombay.

THE pilgrim traffic for Mecca from the port of Bombay is very considerable and involves great expense as well as elaborate precautions. Bombay being a plague-infected city, quarantine for these pilgrims is obligatory according to the Venice Convention. It appears that the quarantine camp provided by the Government has not been sufficiently large and that pilgrims who could not pass into the camp have been roaming in large numbers about the city of Bombay. Many of these people are utterly destitute. An attempt has been made to do away with the quarantine camp but that is at present impossible and the port of embarkation must either be changed or provision for a larger number made in the camp. By removing the port of embarkation to a non-infected place quarantine would become unnecessary and a medical inspection would be sufficient. In this case there would be always the danger of plague breaking out amongst the pilgrims on board ship as it is impossible to detect cases in the incubative stage and the consequences of this accident would be very troublesome. The wisest course is to increase the observation camp according to the number of pilgrims, which would probably prove in the long run the least expensive measure. An announcement is made annually of the numbers of pilgrims who leave India for Mecca but there are no corresponding figures for the numbers who return. Old and infirm as the majority are the mortality amongst them must be considerable and the hardships which these people go through on arrival in the Turkish dominions have been reported upon over and over again. It is also known that the majority of those who do come back to India return penniless and many of them have to be helped to get back to their native places.

A Fresh Census for Bombay City.

The last census indicated that the city of Bombay had decreased in population. This was attributed to plague which in the five years had probably stricken down 100,000 people. Many of the inhabitants had also left the city for the country districts. As the fear of plague has now diminished and the population has apparently again increased it has been urged upon the corporation to take a fresh census. This will be done for the town and island of Bombay on the night of Feb. 9th. It is probable that immigration into the city has made up the population to the old figures and the value of the census for statistical purposes is obvious. The mortality-rate based on the census of 1901 is very high.

Reservoir Leakages and Fever in Bombay City.

For some time past leakages have occurred from the Malabar Hill and Bhandarwada reservoirs in the city of Bombay and the surrounding areas of ground have been sodden and swamped. Associated with this condition these surrounding areas have been fever-stricken. The corporation has now called for a report. Since 1901 the health department has taken steps to keep the tanks themselves free from mosquitoes but the danger covers a much wider area and the necessity of treating all the pools and ditches and surface collections of water as well as the wells, fountains, and drains by an active anti-mosquito campaign is recognised as imperative pending the carrying out of the engineering measures required for the repair of these huge reservoirs. The anopheles mosquitoes have been abundantly found in nearly all parts of the city but the pools and swampy places occasioned by these leakages have been their chief breeding grounds.

The Plague Epidemic.

The plague mortality figures for India show fluctuations which are probably sometimes due to faulty returns. For the week ending Dec. 23rd, 1905, 3170 deaths were recorded but several districts are omitted from the usual list. The details are: Bombay Presidency, 729; United Provinces, 761; Bengal, 639; Central Provinces, 400; the Panjab, 314; Mysore State, 124; and Burma, 77. The figures for the large cities are not published.

The Work of the St. John Ambulance Association in India.

The report for the year of the work of the St. John Ambulance Association in India has just been issued and shows a marked activity in several of the more important and populous centres. A central committee at Simla now governs the Indian branch but the various provincial centres manage their own affairs. The chief work seems to be amongst the European population (also the Parsi) but a considerable amount of instruction has been given to natives. The railways have been very active and a large proportion of their employés have gone through the "first-aid" course. A challenge shield is competed for annually amongst the railways and also amongst the volunteers. In Bombay an ambulance brigade and a ladies' nursing division have been formed and it is proposed to form a reserve to augment the nursing establishment in time of war. The police of Calcutta and Bombay have all been instructed in first aid to the injured and a better organisation has been established in these two cities in the event of accidents. The members of the medical profession appear to have given their services in all cases but it is quite a question whether the time has not come, as in England, when instruction and examination should be paid for.

Jan. 5th.

Obituary.

HARRY CAMPBELL POPE. M.D. LOND., F.R.C.S. ENG.

Dr. H. C. Pope, who died on Jan. 2nd, in his fifty-sixth year, was the son of the late Mr. E. Pope, M.R.C.S. Eng., of Tring. He received his medical education at Liverpool and at University College, London. After taking the M.B. Lond. with honours he became successively medical tutor and demonstrator of anatomy at the Queen's College, Birmingham, and house surgeon to the Seamen's Hospital, Greenwich. Upon the expiration of his term of office he married and settled in practice at Shepherd's Bush. Having taken the F.R.C.S. Eng. in 1876 and graduated M.D. Lond. in 1878 these qualifications, together with his personal character and various gifts, soon gave him a leading position in the western district of London. This was very manifest in connexion with the West London Medico-Chirurgical Society, in which he was constantly put forward in various representative ways by his neighbours and colleagues. He always represented them with dignity and good taste, speaking with ease, sound sense, and a frequent touch of humour, occasionally playfully descending into a pun. He had a calm, easy-tempered, good-natured disposition which made him very pleasant to work with. He filled nearly every possible office in connexion with the West London Medico-Chirurgical Society, being a member of council from its commencement, 25 years ago, and its president in 1899. He also took a very active part in the management of the Medical Defence Union, of which he was a vice-president. Dr. Pope had from the beginning of his entering the professional ranks as a practitioner a large private practice and his patients saw in him not only a valued scientific physician but also an accomplished friend. His chief recreation was music, in which he was well skilled. He played both the piano and the organ, but above all he had a pleasing and powerful baritone voice and was a cultivated singer. Many of our readers will remember the pleasure he has often given them on various social occasions, public and private. In appearance he was a man of portly build, with good features and a quiet expression, although his dark eyes frequently lighted up with the humour already referred to. There are probably few persons of whom it could be more truly said that he was universally liked and trusted and had no enemy. His death was very sudden and a severe blow to his many friends and patients. Able, accomplished, and altogether

devoid of restless ambition but, at the same time, ever ready to do whatever duty or good work lay in his immediate way, his friends, while grieving at his departure, feel that his life is a very pleasant one to look back upon. His personality, much that he said, and more that he did, will be vividly remembered by many people when the celebrity of more prominent public characters will be nothing but the mere memory of a name. He was not a frequent or voluminous contributor to medical literature but in his many quiet speeches at medical societies he contributed altogether a great volume of practical experience and in that manner made public in brief the details of many interesting cases. He was buried in Hammersmith Cemetery, the funeral being attended by many old private friends, including Dr. Frederick T. Roberts, whose friendship dated from Liverpool days, and by official representatives of the societies to which Dr. Pope had belonged. He leaves a family of two sons and three daughters to mourn their loss, the elder son being a student at St. Mary's Hospital.

WILLIAM WINGATE WINGATE SAUL, M.D. HEIDELBERG, M.R.C.S. ENG., L.S.A.

Dr. William Wingate Wingate-Saul, who died on Jan. 22nd at his residence, Fenton-Cawthorne House, Lancaster, was one of the foremost and most respected citizens and public men of the town. About 18 months ago failing health compelled him to give up practice and he was confined to his room for many weeks before the end came. He was the third son of Mr. William Saul of High Ferry House, Sibsey, Lincolnshire, and grandson of Captain B. Kelsey Saul, who commanded the Sibsey volunteers a century ago, and a direct descendant of Colonel John Saul, who, for his gallant defence of Croyland Abbey in the Civil War, received the freedom of King's Lynn. He was born at High Ferry House on July 24th, 1842, and assumed the additional surname of Wingate by deed poll dated June 18th, 1891. His early education was received at King Edward VI. School at Louth—the school of Tennyson, the Lincolnshire Laureate, and Tom Hood—and in due course he studied medicine at St. Bartholomew's Hospital and the University of Heidelberg. In 1867 he took the diplomas of M.R.C.S. Eng. and L.S.A., and in 1870 he graduated as M.D. at Heidelberg. In the last-mentioned year he went to Lancaster at the suggestion of Sir James Paget and Sir Richard Owen to join Mr. Langshaw in partnership, and he succeeded to the practice on the retirement of Mr. Langshaw.

Many public positions have been filled by Dr. Wingate-Saul in Lancaster. For nearly a quarter of a century he was surgeon to the civil and military prisons at Lancaster Castle and had several notable people under his care. For a short time he was on the staff of the Lancaster Infirmary when the institution was situated in Thornham-street, and during the whole of the time he was in practice he was medical officer to the Royal Grammar School and to the Ripley Hospital. For 22 years Dr. Wingate-Saul was an officer in the Duke's Own Yeomanry and always took great interest in everything concerning the regiment. He joined the regiment in June, 1881, with the rank of surgeon-captain. In June, 1901, he was appointed lieutenant-colonel and on his retirement, after 22 years' service, he was raised to the rank of colonel and granted permission to wear the uniform of the regiment. The "Duke's Own," now known as the Duke of Lancaster's Own Imperial Yeomanry, was founded about 1800 and is therefore one of the oldest volunteer cavalry regiments in England. It was brought into special prominence during the Chartist riots of 1818 and the charge of Peterloo consequent thereon.

Dr. Wingate-Saul was the founder of the Lancaster centre of the St. John Ambulance Association. He was the first lecturer for the association in Lancaster, was awarded the medal of the order, and at the time of his death was one of its honorary associates. He was chairman of the local branch of the Royal Society for the Prevention of Cruelty to Animals ever since its formation and assisted the work of the branch materially. He was always in sympathy with the feelings of dumb animals and was particularly emphatic against the use of the now universally condemned tight-lining-rein. He was one of the original members of the County Club at Lancaster; a member of the Red Rose Club, established as a bond of connexion between the past and present officers of Lancashire regiments of militia and yeomanry; and chairman of the Ratepayers' Association

which he assisted to form. His tastes were chiefly in the direction of literature, art, and music. He was for some time president of the Orchestral Society and chairman of the Choral Society. It may be worthy of note that he used at several public performances a Stradivarius violin, purchased by a cousin of his father in 1826. He had played on it since he was a boy and it is described as an exceptionally fine model of Stradivarius's best type of violin. He owned, too, a very fine Amati. Dr. Wingate-Saul was also the possessor of two very fine examples of Romney's work—life-size portraits of the Fenton-Cawthorne family. He was a member of various societies outside Lancaster, such as the Hackney Horse Society, the Polo Pony Breeding Society, and several agricultural societies, including the Royal Agricultural Society of England, with which, however, he ceased to be connected on the council moving the annual fixture to Park Royal near London. Amongst other breed societies with which he was connected may be mentioned the English Kerry and Dexter Herd Book Society and the Large Black Pig Breeders' Society.

For some years Dr. Wingate-Saul was a member of the central committee of the Royal Albert Asylum at Lancaster and he took a warm interest in all concerning the institution and the welfare of the patients. A few years ago he gave to the institution a chalet for the open-air treatment of tuberculous disease. His generosity induced another member of the central committee to do likewise, and the results that have followed this new treatment have been very satisfactory. Dr. Wingate-Saul was a member of the Rowley Lodge of Freemasons and also of the ancient society of John O'Gaunt Bowmen.

The deceased gentleman was a *laudator temporis acti*, a Conservative and a Churchman, a supporter of Church and State of the old-fashioned type. He attributed much of the lack of usefulness of some of the rising generation to the degeneracy brought about by cheap literature. One of the greatest pleasures of his life was a well-arranged reference library, which enabled him to become particularly apt in quotation, anecdote, or illustration. He possessed the pen of a ready writer, and his letters to the local press, if they could be collected and reprinted, would throw interesting sidelights upon local history during the past 30 years. Soon after going to Lancaster he married the eldest daughter of the late Mr. William Storey, J.P., of Fairfield House, who was mayor of Lancaster in 1872-73. Mrs. Wingate-Saul survives him with four sons and two daughters. Those who are interested in coincidences will find matter for reflection in the fact that Dr. Wingate-Saul's father, mother, and brother, like himself, died when they were 63 years of age.

HENRY PARR MALLAM, M.R.C.S. ENG., L.S.A.

By the death of Henry Parr Mallam, which occurred somewhat suddenly on Jan. 19th, one of the most familiar figures in Oxford passes away. He was born in 1838 and was rightly proud of the fact that he had earned his own living from the age of nine years when he was elected to a choristership at Magdalen College. Determining to enter the medical profession he became apprenticed to Dr. Freeborn when about 17 years old and then gained a scholarship at Charing Cross Hospital. Part of the money necessary for his livelihood he had to borrow, but by dint of hard work he was enabled to pay it off within a short time. In 1862 he became L.S.A. and was elected as house surgeon. In the following year he took the diploma of M.R.C.S. Eng. and started practice in Oxford in the same year as partner with Dr. Martin. Their practice lay mainly among the hunting farmers of the neighbourhood and in those days it was possible for a medical man to combine professional work with the active sports of hunting and rowing, both of which occupations appealed greatly to Mallam. Of more sedentary amusements Mallam was fond of whist and of music. With regard to the latter his early training stood him in good stead, while he possessed that much-to-be-envied treasure a real tenor voice. He was for many years a member of the Oxford Orpheus Society and a vice-president of the choral society. Besides his purely professional work he took his share in municipal affairs, serving for many years of his life as a member of the local board. For 42 years he was medical officer to the Oxford workhouse and to the Poor-law school and in these two difficult and important posts he was renowned for his kindness and tact, the former

never degenerating into mere sentiment and the latter containing a large element of shrewdness. His relations with his board were always peculiarly happy. His advice was always ready and thoroughly sound, while he was at once courteous and firm as a professional adviser should be.

The position of a medical man in large practice in a University town is one of great distinction and of corresponding responsibility and there are few positions which give rise to such opportunities for making friendships and, moreover, for criticism or even worse. But Mallam so bore himself that his friendships were many and warm, while the reverse was practically unknown. He was a man of well-balanced judgment, keeping thoroughly abreast of all recent advances in medicine and choosing carefully and adopting what seemed of service. His skill in obstetrics was great and for many years he held the leading practice in this department in Oxford and its neighbourhood. He married a Miss Margetson and the great sorrow of his life was her sudden death after about 18 years of married life. He leaves four daughters and three sons, one of whom, Dr. Ernest Mallam, follows in his footsteps in Oxford.

Mallam belonged to the school of a bygone day; not that we mean that he was in any way fossilised but to those who knew him well and, indeed, to all who came into contact with him his personality was very lovable. Quiet, free from all self-seeking, most kind, with an old-fashioned courtesy full of charm, he took a place in Oxford medical life of much distinction and has left a gap which will be felt by everyone who has had the privilege of his friendship. He was one of those who had the rare gift of making his patients feel that he could aid them directly he came into the room. "I have ever thought," says Manchester Al Mondo, "the right way to dye well, was to live well," and if this can be said of any man it may well be said of Henry Parr Mallam.

WILLIAM AUGUSTUS WEST, L.R.O.P. IREL., L.R.O.S. IREL., L.M.

THE death of Mr. William Augustus West is announced at Sydney, New South Wales, at the early age of 46 years, from pneumonia, followed by pleurisy and heart affection. Mr. William West was the youngest son of the late George White West, barrister-at-law, of Ardenode, co. Kildare, and qualified for his profession in Dublin. He then left for Sydney where he became assistant to, and afterwards partner with, his elder brother, the late Dr. Arthur Annesley West, then practising at the Glebe, a suburb of Sydney. When Dr. Arthur West died in 1885 Mr. William West continued the practice alone. He was well known and highly respected in the city as an able practitioner, and also esteemed for his kindly disposition, during the 22 years he spent in the district. His untimely death occurred on Dec. 11th, 1905, and he leaves a widow and two children to mourn their loss.

FRANCIS FOX, M.R.C.S. ENG., L.S.A., CONSULTING SURGEON TO THE SOUTH DEVON AND EAST CORNWALL HOSPITAL.

Mr. Francis Fox died at his residence, 9, Athenium-terrace, Plymouth, on Jan. 18th, in his ninety-third year. The deceased, who received his professional training in Birmingham and at University College, London, took the diplomas of M.R.C.S. Eng. and L.S.A. in 1838 and 1837 respectively and shortly afterwards commenced practice in Plymouth. He was formerly surgeon to the Plymouth Public Dispensary and had been for many years on the honorary staff of the South Devon and East Cornwall Hospital, being honorary consulting surgeon to that institution at the time of his death. When the cholera outbreak occurred in Plymouth in 1849 Mr. Fox had charge of the cholera hospital and did noble work hand in hand with the late Rev. G. R. Prynne, vicar of St. Peter's. Mr. Fox was one of the oldest members of the Royal Western Yacht Club and took a great interest in yachting matters. In his younger days he was well known as a skilful operating surgeon and was one of the first surgeons in the West of England who performed ovariectomy with a successful result. Mr. Fox leaves a son and daughter. He will be missed in Plymouth where he was highly esteemed and respected, for there have been few inhabitants of the "three towns" better known in days gone by.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At the examination held in January the following candidates passed in the subjects indicated:—

Surgery.—J. A. Kilpatrick (Section II.), King's College Hospital; and S. Zweifelback (Section II.), Koenigsberg.
Forensic Medicine.—L. O. W. Brigstocke, Oxford and St. George's Hospital.
Midwifery.—J. P. E. Henery, St. George's Hospital; O. Mulholland, Belfast; and H. F. Wight, Guy's Hospital.
 The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—J. A. Kilpatrick and S. Zweifelback.

UNIVERSITY OF CAMBRIDGE.—Mr. H. O. Jones has been appointed deputy for the Jacksonian professor, Sir James Dewar, for the present term.—The following degrees were conferred at the Congregation on Jan. 18th:—

M.D.—A. C. Hudson, Trinity.
 Sc.D.—H. J. H. Fenton, Christ's.
 M.C.—C. B. Goulden, Downing.
 M.B.—N. C. Carver, King's; W. R. Honeybourne, Peterhouse; R. Pattock, Emmanuel; and W. P. Williams, Downing.
 B.C.—P. Shingleton Smith, King's; A. D. Brunwin, H. T. Gray, and A. H. Miller, Trinity; F. F. Leighton, T. M. Neathy, and G. C. E. Simpson, St. John's; J. O. L. Roberts, Clare; C. Lillingston, Pembroke; C. H. W. Page, Corpus; G. W. de P. Nicholson, Jesus; G. L. Cox, Christ's; C. T. Scott, Sidney; and W. D. Keyworth, Selwyn Hostel.

LITERARY INTELLIGENCE.—Mr. William Heine-mann will publish in the spring under the title of "A Handbook of Metabolism," an English translation of the second German edition of von Noorden's "Lehrbuch des Stoffwechsels," edited by Dr. Walker Hall.

Mr. J. Collingwood Thompson, L.R.C.P. & S. Edin., L.F.P.S. Glasg., who died on Jan. 13th at Bank Head, Fencehouses, Co. Durham, was only 33 years of age, and his early death from acute pneumonia will come as a surprise to many who only knew him in his usual robust health. Though he qualified by taking the triple qualification of Edinburgh and Glasgow he was originally a student at the Durham University College of Medicine. For a time he practised in North Northumberland but several years ago settled at Bank Head where he soon became very well known to the mining population of that district. Mr. Thompson's mother, who survives to mourn his death, was a niece of the famous admiral, Lord Collingwood.

BRITISH GYNÆCOLOGICAL SOCIETY.—The annual dinner of this Society was held on Jan. 17th, at the Monaco, London, Dr. W. Alexander, the President, being in the chair. The toast of "The British Gynæcological Society" was proposed in felicitous terms by Dr. T. W. Eden. The President, in responding, gave some details of the progress and prosperity of the society. The foundation meeting was held on Dec. 27th, 1884, and its first president was Dr. A. Meadows. The society had existed for 21 years and its Fellows numbered nearly 500. He referred with pride to the journal of the society and his complimentary remarks concerning the work of the honorary secretaries, Dr. S. J. Aarons and Dr. S. Savage, elicited great applause. In connexion with the proposed amalgamation of medical societies the President mentioned that the British Gynæcological Society had given its adhesion to the proposed scheme. Dr. H. M. Macnaughton-Jones was entrusted with the toast of "The Services," which he proposed in an eloquent and impressive speech. Surgeon-General A. H. Keogh, C.B., Director-General of the Army Medical Service, in the course of his reply to this toast observed that the medical profession had a definite relation to war and explained how a campaign without a properly equipped medical department was bound to be a losing one and the sooner the medical profession awoke to the fact the better it would be for all concerned. The army authorities were responsible for an enormous number of women and children scattered throughout the Empire and it was part of the duty of the Army Medical Service to help these people. Medical officers were now trained specially for the work and anyone who visited the hospitals at Aldershot would give full credit for the excellent results obtained there. The enjoyment of the evening was enhanced by a well-arranged musical programme.

THE GENERAL ELECTION.—The following members of the medical profession have been returned to Parliament since our last issue: Mr. R. Ambrose, L.R.C.P., L.R.O.S. Edin., re-elected for West Mayo; Mr. R. J. Price, M.R.C.S., re-elected for East Norfolk; Dr. A. R. Rainy, M.B., O.M. Edin., elected for the Kilmarnock Burghs; Sir G. S. Robertson, K.O.S.I., M.R.C.S., L.S.A., I.M.S. (retired), elected for Bradford (Central), and Dr. V. H. Rutherford, M.B. Cantab., &c., elected for the Brentford Division of Middlesex. Amongst those who have lost their seats are Sir Michael Foster, K.C.B., M.B. Lond., and Dr. O. F. Hutchinson, M.D. Edin.

SOCIETY OF ARTS.—At an ordinary meeting of the Society of Arts held on Jan. 17th Dr. W. A. Aikin read a paper on the Scientific Aspects of Voice Development. He said that in the production of the voice three factors were involved—namely, the breath, the vocal reed, and the resonator. On the subject of the breath he said that the voice required a large and well-controlled volume of air in the chest and he discussed the relations of costal and diaphragmatic breathing at some length. The best effect was produced by what he called "central breathing," in which during inspiration the lower ribs were raised and fixed and the diaphragm was drawn down so that the upper part of the abdomen (but not its lower part) was caused to bulge forwards. The first part of the vocal expiration was accomplished by the diaphragm and the ribs afterwards began to descend. Contrary to the normal rhythm of respiration, the intake was usually rapid, and in singing the output was carefully distributed over a period which might be as long as 15 seconds. Dr. Aikin then described the mechanism by which the "vocal membranes" created sounds and said that their action was that of an acoustic reed. He next mentioned a variety of objections to the use of the manœuvre called "coup de glotte," or intentional closing of the sphincter, constituted mainly by the ventricular bands—two muscular folds immediately above the vocal membranes. He said that the variation of the pitch of the note depended upon the range throughout which the tension of the vocal membranes could be varied; this was entirely under the control of mental sound perception and in order to start a note without any uncertainty or hesitation it must be heard in the mind beforehand. The third factor in the production of the voice was the resonator or hollow spaces of the throat, mouth, and nose. The resonator could be sounded by itself, as in whispering—that is, without any reed note—but it was not possible to hear the reed note by itself since it could never avoid passing through the resonator. Thus it arose that every sounding note or vowel in language was associated with a particular position of the resonator. The power of using the vocal reed existed almost from the moment of birth but the management of the resonator was wholly acquired by education, just as with other voluntary muscular actions. The vocal reed was virtually the instinctive instrument of the emotions while the resonator was the cultivated instrument of the intellect. Different views on the subject of voice resonance have been held by different observers. Helmholtz and those who copied from him described the vowel A (ah) as being formed by a funnel-shaped chamber increasing with tolerable uniformity from the larynx to the lips. Dr. Aikin regarded this as an anatomical error and maintained that the resonator consisted of two chambers meeting at right angles by a somewhat constricted orifice in the throat, opposite which point there was a communication with a third chamber—namely, the nose. He demonstrated on himself the existence of the double or two-chambered resonator by percussing it at different times on his cheek and neck, eliciting in each case a series of ascending or descending tones according to the pitch of successive whispered sounds. He further showed that the two chambers could be made to act in unison and then demonstrated the nodal point at their junction by means of a tuning fork which sounded when held in the cavity of the mouth, was silent when advanced to the nodal point, and sounded again when advanced still farther to the pharyngeal cavity. Of the two chambers the upper one was represented by the mouth; it was roughly hemispherical with a flat floor, a domed roof, an almost circular opening in front, and an oval opening at the back passing down into the chamber of the neck, which was composed of the pharynx and larynx. This second chamber was expanded by holding the head and back straight, by raising the ribs, and by

which he assisted to form. His tastes were chiefly in the direction of literature, art, and music. He was for some time president of the Orchestral Society and chairman of the Choral Society. It may be worthy of note that he used at several public performances a Stradivarius violin, purchased by a cousin of his father in 1826. He had played on it since he was a boy and it is described as an exceptionally fine model of Stradivarius's best type of violin. He owned, too, a very fine Amati. Dr. Wingate-Saul was also the possessor of two very fine examples of Romney's work—life-size portraits of the Fenton-Cawthorne family. He was a member of various societies outside Lancaster, such as the Hackney Horse Society, the Polo Pony Breeding Society, and several agricultural societies, including the Royal Agricultural Society of England, with which, however, he ceased to be connected on the council moving the annual fixture to Park Royal near London. Amongst other breed societies with which he was connected may be mentioned the English Kerry and Dexter Herd Book Society and the Large Black Pig Breeders' Society.

For some years Dr. Wingate-Saul was a member of the central committee of the Royal Albert Asylum at Lancaster and he took a warm interest in all concerning the institution and the welfare of the patients. A few years ago he gave to the institution a chalet for the open-air treatment of tuberculous disease. His generosity induced another member of the central committee to do likewise, and the results that have followed this new treatment have been very satisfactory. Dr. Wingate-Saul was a member of the Rowley Lodge of Freemasons and also of the ancient society of John O'Gaunt Bowmen.

The deceased gentleman was a *laudator temporis acti*, a Conservative and a Churchman, a supporter of Church and State of the old-fashioned type. He attributed much of the lack of usefulness of some of the rising generation to the degeneracy brought about by cheap literature. One of the greatest pleasures of his life was a well-arranged reference library, which enabled him to become particularly apt in quotation, anecdote, or illustration. He possessed the pen of a ready writer, and his letters to the local press, if they could be collected and reprinted, would throw interesting sidelights upon local history during the past 30 years. Soon after going to Lancaster he married the eldest daughter of the late Mr. William Storey, J.P., of Fairfield House, who was mayor of Lancaster in 1872-73. Mrs. Wingate-Saul survives him with four sons and two daughters. Those who are interested in coincidences will find matter for reflection in the fact that Dr. Wingate-Saul's father, mother, and brother, like himself, died when they were 63 years of age.

HENRY PARR MALLAM, M.R.O.S. ENG., L.S.A.

By the death of Henry Parr Mallam, which occurred somewhat suddenly on Jan. 19th, one of the most familiar figures in Oxford passes away. He was born in 1838 and was rightly proud of the fact that he had earned his own living from the age of nine years when he was elected to a choristership at Magdalen College. Determining to enter the medical profession he became apprenticed to Dr. Freeborn when about 17 years old and then gained a scholarship at Oharing Cross Hospital. Part of the money necessary for his livelihood he had to borrow, but by dint of hard work he was enabled to pay it off within a short time. In 1862 he became L.S.A. and was elected as house surgeon. In the following year he took the diploma of M.R.O.S. Eng. and started practice in Oxford in the same year as partner with Dr. Martin. Their practice lay mainly among the hunting farmers of the neighbourhood and in those days it was possible for a medical man to combine professional work with the active sports of hunting and rowing, both of which occupations appealed greatly to Mallam. Of more sedentary amusements Mallam was fond of whist and of music. With regard to the latter his early training stood him in good stead, while he possessed that much-to-be-envied treasure a real tenor voice. He was for many years a member of the Oxford Orpheus Society and a vice-president of the choral society. Besides his purely professional work he took his share in municipal affairs, serving for many years of his life as a member of the local board. For 42 years he was medical officer to the Oxford workhouse and to the Poor-law school and in these two difficult and important posts he was renowned for his kindness and tact, the former

never degenerating into mere sentiment and the latter containing a large element of shrewdness. His relations with his board were always peculiarly happy. His advice was always ready and thoroughly sound, while he was at once courteous and firm as a professional adviser should be.

The position of a medical man in large practice in a University town is one of great distinction and of corresponding responsibility and there are few positions which give rise to such opportunities for making friendships and, moreover, for criticism or even worse. But Mallam so bore himself that his friendships were many and warm, while the reverse was practically unknown. He was a man of well-balanced judgment, keeping thoroughly abreast of all recent advances in medicine and choosing carefully and adopting what seemed of service. His skill in obstetrics was great and for many years he held the leading practice in this department in Oxford and its neighbourhood. He married a Miss Margetson and the great sorrow of his life was her sudden death after about 18 years of married life. He leaves four daughters and three sons, one of whom, Dr. Ernest Mallam, follows in his footsteps in Oxford.

Mallam belonged to the school of a bygone day; not that we mean that he was in any way fossilised but to those who knew him well and, indeed, to all who came into contact with him his personality was very lovable. Quiet, free from all self-seeking, most kind, with an old-fashioned courtesy full of charm, he took a place in Oxford medical life of much distinction and has left a gap which will be felt by everyone who has had the privilege of his friendship. He was one of those who had the rare gift of making his patients feel that he could aid them directly he came into the room. "I have ever thought," says Manchester Al Mondo, "the right way to dye well, was to live well," and if this can be said of any man it may well be said of Henry Parr Mallam.

WILLIAM AUGUSTUS WEST, L.R.O.P. IREL., L.R.O.S. IREL., L.M.

THE death of Mr. William Augustus West is announced at Sydney, New South Wales, at the early age of 46 years, from pneumonia, followed by pleurisy and heart affection. Mr. William West was the youngest son of the late George White West, barrister-at-law, of Ardenode, co. Kildare, and qualified for his profession in Dublin. He then left for Sydney where he became assistant to, and afterwards partner with, his elder brother, the late Dr. Arthur Annesley West, then practising at the Glebe, a suburb of Sydney. When Dr. Arthur West died in 1885 Mr. William West continued the practice alone. He was well known and highly respected in the city as an able practitioner, and also esteemed for his kindly disposition, during the 22 years he spent in the district. His untimely death occurred on Dec. 11th, 1905, and he leaves a widow and two children to mourn their loss.

FRANCIS FOX, M.R.O.S. ENG., L.S.A., CONSULTING SURGEON TO THE SOUTH DEVON AND EAST CORNWALL HOSPITAL.

Mr. Francis Fox died at his residence, 9, Athenæum-terrace, Plymouth, on Jan. 18th, in his ninety-third year. The deceased, who received his professional training in Birmingham and at University College, London, took the diplomas of M.R.O.S. Eng. and L.S.A. in 1838 and 1837 respectively and shortly afterwards commenced practice in Plymouth. He was formerly surgeon to the Plymouth Public Dispensary and had been for many years on the honorary staff of the South Devon and East Cornwall Hospital, being honorary consulting surgeon to that institution at the time of his death. When the cholera outbreak occurred in Plymouth in 1849 Mr. Fox had charge of the cholera hospital and did noble work hand in hand with the late Rev. G. R. Prynn, vicar of St. Peter's. Mr. Fox was one of the oldest members of the Royal Western Yacht Club and took a great interest in yachting matters. In his younger days he was well known as a skilful operating surgeon and was one of the first surgeons in the West of England who performed ovariectomy with a successful result. Mr. Fox leaves a son and daughter. He will be missed in Plymouth where he was highly esteemed and respected, for there have been few inhabitants of the "three towns" better known in days gone

Notes, Short Comments, and Answers to Correspondents.

KISSING THE BOOK.

WE have upon many previous occasions referred to the unnecessary, unclean, and disgusting fashion of taking an oath provided by the English legislature, and have compared it with the cleanly form of oath "usually administered in Scotland." Relief upon this point was given to witnesses and others who have to take oaths by the Oaths Act of 1888. This Act, however, is unknown to most ordinary citizens and although probably known to commissioners for oaths and county court judges is often not acted upon as it should be. It is by no means uncommon to see in reports of trials the presiding official, be he judge or magistrate, make disparaging remarks to witnesses who desire to be sworn in the Scottish fashion. This being so we are glad to see that in a case which came before Sir Forrest Fulton, the Recorder, in the Lord Mayor's Court on Jan. 22nd, a witness objected to kiss the book and desired to be sworn in the Scottish fashion. Sir Forrest Fulton is reported as saying that he wished such requests were made more frequently. Addressing Mr. Wallace, K.C., M.P., who was engaged in the case, the Recorder expressed a hope that he, Mr. Wallace, would endeavour to get Parliament to make the Scottish form of oath universal. We quite agree with the Recorder, but in the meantime we may remind our readers that any one of them has a right to be sworn in the Scottish fashion if he so desires it and that no official has any business to make any difficulty about the matter. If, says the Oaths Act, 1888, any person desires to be sworn after the manner in which an oath is usually administered in Scotland, "he shall be permitted to do so and the oath shall be administered to him in such form and manner without further question." From a paragraph which appears in the letter from our Liverpool correspondent in another column it would seem that both the medical officer of health and the officials of the Birkenhead police court are unaware of the provisions of the Oaths Act.

A WARNING TO MEDICAL MEN.

HERE is an alcoholic individual who, when last heard of, was impersonating a medical man in singularly ingenious and mischievous circumstances. He recently applied, while apparently the worse for drink, at a provincial hospital, where he gave the name of the resident medical officer at another provincial hospital, and asked for assistance and a bed. The sister-in-charge of the hospital accordingly gave him the address of one of the members of the medical staff, as she could not herself take the responsibility of admitting him. On him the imposter called and again said that he was Dr. —, the resident medical officer of — hospital, adding that he had "been on the loose" and had had an attack of hæmatemesis in the train and felt very ill. The medical man, noting his obviously sad plight, paid for his rooms in a neighbouring hotel, where the next morning he disappeared. It is possible that other medical men may be similarly victimized by this ingenious person who, although he is obviously not fit subject for medical care, is not a medical man and ought to be punished for assuming the name and address of a medical man in this singularly offensive manner.

SUPERCHILARY GYMNASTICS.

To the Editors of THE LANCET.

SIR,—I have read "Harlequin's" letter in THE LANCET of Jan. 20th, 1906. I possess the powers he writes of and am able to lift and to press the eyebrows alternately and simultaneously. I have also some over over the external muscles of the ears and can move both ears pretty freely simultaneously. These powers are, I believe, rather uncommon but the possessor of the latter accomplishment is perhaps of no altogether congratulated upon it, as it is by some regarded as a sine attribute. I prefer to regard it as an indication of an advanced stage in the evolutionary process.

Jan. 20th, 1906.

I am, Sirs, yours faithfully,

"DARWIN."

To the Editors of THE LANCET.

SIR,—With reference to "Harlequin's" letter in THE LANCET of Jan. 20th, p. 193, both my sister and I have amused ourselves for some ears by depressing one eyebrow by elevating the other. Curiously enough, we elevate the left and depress the right but not vice versa, although I believe with sufficient practice this might be attained. Here is, however, to my thinking, no great advantage to be derived from this accomplishment.—I am, Sirs, yours faithfully,

Jan. 20th, 1906.

A. B.,
Teacher of Swedish Gymnastics.

To the Editors of THE LANCET.

SIR,—I was able to perform the feat of raising one eyebrow while depressing the other at my first attempt after seeing "Harlequin's" letter. I do not know that it is a power possessed by every individual,

but perhaps with some practice most people would be able to acquire it, as also, I believe, one can (with practice) make use of the muscles of the ears to make them move by fixing the occipito-frontalis muscle.

I am, Sirs, yours faithfully,

Jan. 23rd, 1906.

CLASSIC.

To the Editors of THE LANCET.

SIR,—It may interest "Harlequin" to know that I have been able to perform the feat he mentions for some time, since I was a boy at school. I have a brother who can raise one eyebrow and depress the other but only on one side and not alternately. It is not a very hard matter to accomplish the feat with a little practice if one commences young enough. I think that it is on a par with the voluntary movement of other muscles which are not often used voluntarily, such as the small extrinsic muscles of the ear and the occipito-frontalis. With many of the lower animals the use of these muscles is an every-day occurrence and doubtless it was so with our primal ancestors. I inclose my card if "Harlequin" cares to make further inquiries.

I am, Sirs, yours faithfully,

H. B. D.

THE NEW MIDWIFE.

WITH the advent of the new midwife as moulded by the Midwives Act has come the natural desire on the part of "local supervising authorities" that the midwives under them should be instructed as to their duties. We recently published a note upon a code of such instructions in use in Manchester and now the Salop local supervising authority has followed suit and has issued instructions to its midwives. These instructions, which are based more or less upon the Manchester code, are signed by Dr. J. Wheatley, the county medical officer of health. They are sound and clearly expressed but in one place we think that an alteration is required. On p. 4, which contains the instructions dealing with the management of labour, the midwife is instructed to boil her nail-brush for three minutes. We are not aware of the fiscal condition of the nail-brush trade, but if it be one of our disappearing industries the regulation in question should give it a fillip, for we are sure that hardly any nail-brush could stand boiling for a period of three minutes more than twice or thrice. As the brush is not used for the patient but for scrubbing the nurse's hands, which are already surgically unclean, and as hot soap-and-water are to a fairly high extent bactericidal we think that it would be quite enough to soak the nail-brush in some disinfectant before using it. Unless the local supervising authority is prepared to supply nail-brushes we fancy that the local midwife will not comply with the regulation in question.

CONCERNING TUCKER: A WARNING.

A person named Tucker, who was sentenced to four months' imprisonment, at the end of 1904, for attempted fraud in connexion with the sale of a medical practice to Mr. D. L. Lindsay of Liverpool, has sent us an advertisement for insertion in THE LANCET, which runs as follows:—

"Wanted, a gentleman to manage a country practice, value £300, with appointments worth £50. No premium being asked for practice, he must be able to purchase the latter."

The replies were to be sent to THE LANCET office. We are inserting the suggested advertisement in a more prominent part of the journal than that usually accorded to such announcements as a warning to those in search of a practice to steer clear of Tucker. He addresses his letter from "Napton, Rugby," and signs himself "W. E. Tucker," but he is known to us as D. Tucker. He is not a medical man and previously to the four months' imprisonment alluded to was fined £10 and £3 costs for forging death certificates in the name of Dr. Henry Gould. It may be mentioned that the name of Mr. W. E. Tucker occurs in the Medical Register, where he is stated to be resident in Bermuda—no doubt, in D. Tucker's opinion, a fairly safe distance from Rugby and one enabling a personation scheme to be safely tried. It would be interesting to us to learn whether a Mr. "W. E. Tucker," who in a letter which has been forwarded to this office by the recipient, addressed from 101, Everton-road, Liverpool, dated Sept. 21st, 1904, signed himself "D." Tucker, is the holder of the appointments therein mentioned, worth £50! Further information concerning Tucker may be found in THE LANCET of Oct. 1st, 1904, p. 934, and of Dec. 24th, 1904, p. 1811. It seems to us that the police and the General Medical Council might both have something to say to Tucker. Any help we can give is theirs.

THE PATENT "S.Y.P." TEAPOT.

NOTHING could be simpler than the management of this teapot for the preparation of an infusion of tea containing a minimum of astringent principles. We have on a previous occasion described its main features but recently some further improvements have been made. Formerly the infuser consisted of a loose perforated metal container, whereas in the new design the infuser is part and parcel of the pot itself, the whole being made of Wedgwood cream-coloured ware. When the teapot is in its normal position the infuser is situated immediately under the dome of the pot, so that the leaves may be separated from the infusion. In making the tea infusion the leaves are placed in the infuser and the pot is filled in such a position that the spout points upwards and the handle is below. Hot water is then poured on the leaves and when it is considered that they have been sufficiently infused the

drawing the larynx down by the sterno-thyroid muscles. The expansion of this chamber was very important for the resonance of the voice but it was not essential to the actual formation of the vowels. In establishing the best possible resonant positions for the vowels the lower chamber must coöperate with the mouth. This lower chamber was in shape like a bag—narrow above where it entered the back of the mouth and wider below where it included the larynx, with the vocal membranes in the middle of its floor. The vowel sound Ah whispered with the mouth open and the teeth held an inch apart has a resonant pitch for men very close to C or O sharp in the treble stave and for women one about a third higher—namely, E flat or E. With children of both sexes the pitch is higher still and Dr. Aikin was therefore unable to accept the opinion of Helmholtz who believed that resonance was the same in men, women, and children. On Dr. Aikin's "resonator scale" all whispered vowel sounds are represented by a series of 12 notes, the lowest being that of "root" which is F in the first space of the treble stave and the highest being that of "leap" which goes up to C above the treble. He subsequently discussed the subject of the harmonic reinforcement of the voice and concluded by urging the necessity of making the study of phonology a part of the education not only of professional voice trainers but also of preachers and teachers in general. After the address he sat in front of a mirror and by means of a laryngoscope showed various movements and positions of his own larynx to several of the audience who stood behind him and looked into the mirror over his shoulder.

PRESENTATION TO A MEDICAL PRACTITIONER.—There was a large gathering at the White Hart Assembly Rooms, Tetbury, Gloucestershire, on Jan. 19th, when Sir Nigel Kingscote, on behalf of the subscribers, presented Mr. William Wickham, M.R.C.S. Eng., L.S.A., who is retiring from active work after 45 years' practice in Tetbury and the district, with an illuminated address containing the names of 173 subscribers, a silver inkstand (a copy of William III. style), and a cheque for 300 guineas as a mark of their high appreciation and respect.

MEDICAL MAGISTRATES.—Mr. Norman Henry Lawrence, L.R.C.P., L.R.C.S. Edin., has been placed on the commission of the peace for the district of Laingsburg, and Mr. Charles William Browne, M.R.C.S. Eng., L.S.A., on the commission of the peace for the district of Taungs, British Bechuanaland, South Africa.

INSANITY IN RUSSIA.—The *Pharmatzevitcheskii Vestnik* says that the recent troubles in Moscow have been accompanied by numerous cases of insanity and that the local Moscow hospitals are full of patients suffering from mental disturbance.

TIVERTON INFIRMARY.—Mr. J. Coles has given a house adjoining the Tiverton Infirmary to be used for a nursing institution. He has also given £500 to defray the cost of the necessary alterations.

UNIVERSITY OF OXFORD: DEGREE DAYS.—The following are the degree days appointed for the present term: Saturday, Jan. 27th; Thursday, Feb. 15th; and Thursday, March 15th.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

ABERDEEN. PETER H., M.D. Glasg. & Lond., has been appointed Honorary Aural Surgeon to the Royal Caledonian Asylum, Banbury, Herts.

BALL, J. BRANLEY, L.D.S. R.C.S. Eng., has been appointed Dental Surgeon to the Royal Hospital School, Greenwich, S.E.

COX, FRANKLIN, M.R.C.S., L.R.C.P. Lond., has been appointed District Medical Officer for the Clifton Union.

CUNNINGHAM, H. H. B., M.D. Brux., F.R.C.S. Irel., has been appointed Chief Clinical Assistant to the Royal London Ophthalmic Hospital.

DONSON, MARGARET D., M.D. Lond., has been appointed Pathologist to the West Riding Asylum, Wakefield.

FITZWILLIAMS, DUNCAN C. L., M.D., Ch.B., F.R.C.S. Edin., has been appointed Casualty Officer to the Hospital for Sick Children, Great Ormond-street.

GABRIEL, G. C., M.D. Cantab., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Singleton District of the county of Sussex.

GRANT, J. DUNDAS, M.D. Edin., F.R.C.S. Edin., has been appointed Honorary Aural Surgeon to the Royal Caledonian Asylum, Banbury, Herts.

HARRIS, HERBERT, M.D. Edin., has been appointed Honorary Medical Officer to the Rockdale Infirmary.

LAVAL, EVARISTE, M.B. Edin., has been appointed Assistant Medical Officer to the Warneford Mental Asylum, Oxford.

LYSTER, ROBERT ARTHUR, M.B., Ch.B. Lond., D.P.H., B.Sc. in Public Health, has been appointed Assistant County Medical Officer of Health to the West Riding County Council.

MILLER, JAMES WESTER, M.B., Ch.B. Aberd., has been appointed Assistant Medical Officer at the Dorset County Asylum.

MONTGOMERIE, HUGH MAYER, M.D., C.M. Edin., has been appointed Physician to the West Cornwall Infirmary, Penzance.

MONTGOMERY, JAMES BARCLAY, M.D. Glasg., F.R.C.P. Lond., M.R.C.S., has been appointed Honorary Physician to the West Cornwall Infirmary, Penzance.

MURRAY, WILLIAM, M.D., C.M. Edin., has been re-appointed Medical Officer of Health of the Warming (Gloucestershire) Rural District Council for three years.

POLLOCK, W. B. INGLIS, M.D. Glasg., has been appointed Pathologist and Bacteriologist to the Glasgow Eye Infirmary.

SUTCLIFFE, ANIELLA, M.B., Ch.B. Edin., has been appointed Clinical Assistant to the Southern Branch of the Leeds Public Dispensary.

SYMONS, JOHN, M.R.C.S., L.S.A., J.P., has been appointed Surgeon to the West Cornwall Infirmary, Penzance.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BARNSELY, BECKETT HOSPITAL.—House Surgeon. Salary £100.
BRADFORD POOR LAW HOSPITAL AND WORKHOUSE.—Resident Assistant Medical Officer, unmarried. Salary £100, with rations, apartments and washing.

BURTON-ON-TRENT INFIRMARY.—House Surgeon. Salary £120 per annum, with rooms, board, coal, and light.

CANCER HOSPITAL, Fulham-road, London, S.W.—Senior House Surgeon for six months. Salary £80 per annum, with board and residence.

CANTERBURY, KENT AND CANTERBURY HOSPITAL.—House Physician also House Surgeon, both unmarried. Salary in each case £30 a year, with board and lodging.

CHELTEMER GENERAL HOSPITAL.—Surgeon-in-Charge of Branch Dispensary, unmarried. Salary £30 per annum, with board and lodging.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—Physician.

HALIFAX, ROYAL INFIRMARY.—Third House Surgeon, unmarried. Salary £50 per annum, with residence, board, and washing.

HOSPITAL FOR SICK CHILDREN, Great Ormond street, London, W.C.—Assistant Casualty Medical Officer, unmarried, for six months. Salary £20, with board and residence. Also House Physician, unmarried, for six months. Salary £20, with board and residence.

LEEDS GENERAL INFIRMARY.—Resident Medical Officer. Salary £100 per annum, with board, residence, and washing.

LEICESTER INFIRMARY.—Assistant House Physician for six months. Salary at rate of £50 per annum, with board, lodging, and washing.

MARGATE, ROYAL SEA BATHING HOSPITAL.—Resident Surgeon. Salary at rate of £80 and £120 per annum, with board and residence.

POPULAR HOSPITAL FOR ACCIDENTS, Poplar, E.—Assistant House Surgeon for six months. Salary at rate of £20 per annum, with board and residence.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.—Assistant Resident Medical Officer for four months. Salary at rate of £50 per annum, with board, residence, and washing.

ST. MARK'S HOSPITAL FOR FISTULA AND OTHER DISEASES OF THE RECTUM, City-road, E.C.—House Surgeon. Salary £50 per annum, with board and washing.

ST. MARY'S HOSPITAL MEDICAL SCHOOL, Paddington, W.—Lecturer on Physics. Salary £100 per annum.

SCARBOROUGH HOSPITAL AND DISPENSARY.—Junior House Surgeon, for six months, renewable. Salary £80 per annum, with board and residence.

SHEFFIELD ROYAL HOSPITAL.—Honorary Dental Officer.

SIERRA LEONE, PRINCESS CHRISTIAN HOSPITAL, Freetown, West Africa.—Medical Officer. Salary £250 a year and rooms.

SUNDERLAND INFIRMARY.—House Physician and Third House Surgeon. Salary £80 per annum, with board, residence, and washing.

Births, Marriages, and Deaths.

BIRTH.

MORGAN.—On Jan. 19th, at Westcliff-on-Sea, the wife of W. Harmon Morgan, M.R.C.S., L.R.C.P. Lond., of a daughter.

DEATHS.

DE FAECK.—On Jan. 18th, at his residence in London, William Frederick de Faeck, M.D., M.R.C.S. Eng., Surgeon-General (retired), I.M.S.

MALLAM.—On Jan. 19th, at High-street, Oxford, suddenly, after a short illness, Henry Part Mallam, M.R.C.S.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Beddard: Practical Medicine.
UNIVERSITY COLLEGE HOSPITAL (Gower-street, W.C.).—4 P.M. Clinical Lecture.—Dr. J. R. Bradford: Malignant Endocarditis

THURSDAY (1st).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M. Mr. Hutchinson: Clinique. (Surgical.) 5.15 P.M. Lecture.—Mr. A. H. Tubby: Surgical Diseases of Children.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. Baldwin: Practical Surgery.

CHARING CROSS HOSPITAL.—4 P.M. Dr. Galloway: Demonstration of Medical Cases. (Post-Graduate Course.)

SAMARITAN FREE HOSPITAL FOR WOMEN (Marylebone-road, N.W.).—3 P.M. Lecture.—Mr. Malcolm: On Fibroids.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester-square, W.C.).—6 P.M. Dr. M. Dockrell: Syphilis: I., Miliary and Primary Invasion (Constitutional and Local). (Cheslerfield Lecture.)

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (7, Fitzroy-square, W.).—5 P.M. Lecture.—Mr. J. Berry: The Surgery of Pulmonary Cavities. (Post-Graduate Course.)

HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.).—4 P.M. Lecture.—Dr. F. J. Poynton: Some Hepatic Affections in Children.

FRIDAY (2nd).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M. Mr. A. Lawson: Clinique. (Eye.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. B. J. Reece: Food and Disease.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury, W.C.).—3.30 P.M. Clinical Lecture.—Dr. Batten: Myasthenia Gravis.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—4.30 P.M. Clinical Lecture.—Dr. G. N. Meschen: Acne and its Treatment.

ROYAL INSTITUTION OF GREAT BRITAIN (Albemarle-street, W.).—9 P.M. Prof. S. P. Thompson: The Electric Production of Nitrates from the Atmosphere.

ATURDAY (3rd).—ROYAL INSTITUTION OF GREAT BRITAIN (Albemarle-street, W.).—3 P.M. Mr. J. W. Gordon: Advances in Microscopy. (Lecture I.)

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. II. of 1905, which was completed with the issue of Dec. 30th, were given in THE LANCET of Jan. 6th, 1906.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1905 are now ready. Bound in cloth, gilt lettered, price 18s., carriage extra.

Cases for binding the half year's numbers are also ready. Cloth, gilt lettered, price 2s., by post 2s. 3d.

To be obtained on application to the Manager, accompanied by remittance.

THE LANCET AT THE RAILWAY BOOKSTALLS.

READERS who usually obtain their copies of THE LANCET at the bookstalls on the Great Western, the London and North Western, and the minor systems in connexion with these railways, are requested to communicate with the Manager, 423, Strand, London, W.C., if they experience any difficulty in getting copies of THE LANCET at these bookstalls, Messrs. W. H. Smith and Son's connexion with them having now terminated.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsgagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	 £1 12 6	One Year	 £1 14 8
Six Months	 0 16 3	Six Months	 0 17 4
Three Months	 0 8 2	Three Months	 0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

THE LANCET Office, Jan. 25th, 1906.

During the week marked copies of the following newspapers have been received:—*Siam Observer*, *Sierra Leone Weekly News*, *Express and Echo* (Deron), *Army and Navy Gazette*, *Islington Gazette*, *Hamptstead Express*, *Globe*, *Belfast Whig*, *Birmingham Weekly Post*, *Sun*, *Sheffield Telegraph*, *Glasgow Citizen*, *Yorkshire Observer*, *Leicester Advertiser*, *Portsmouth Independent*, *Newcastle Chronicle*, *York Herald*, *Notts Express*, *Bury Times*, *Middlesex County Times*, *Manchester Guardian*, &c.

pot is returned to its normal position. The infusion is thus separated from the leaves, the latter being held up in the infuser at the top of the teapot. This arrangement not only prevents a prolonged stewing of the tea but it provides also for the retention of the bouquet and fragrant qualities of the tea, for although the leaves are withdrawn from the water they are left inside the closed teapot. The "S Y P" teapot may be obtained from the Inventors and Investors' Corporation, Limited, of 35, Bucklersbury, Bank, E C

MARRIED COUPLES "WITHOUT INCUMBRANCES"

His honour Judge Emden recently had a witness before him in a case at the Lambeth county court who spoke of a man and his wife as being "without incumbrances," upon which the judge said "I presume you mean children when you speak of incumbrances," and added when the witness assented "Say children, then. To refer to children as incumbrances either in speaking or in advertisements for persons wanted to fill situations is only helping the present decline in the birth rate." He might have added that the too general practice to which he thus alluded of excluding married people with families from the opportunity of earning their livelihood encourages the pernicious traffic in pretended abortifacients as well as the actual perpetration of the crimes of procuring abortion and child murder.

THE SPARKLET SELTZOGENE

Those who have had occasion to use the old form of seltzogene with its effervescing powders will easily recognise the advantages offered by the new sparklet seltzogene or sparklogene. To begin with, the effervescing powders are dispensed with altogether in the sparklogene, and when we recall the trouble involved in placing powders in the upper container, in keeping particles of them out of the aerated liquid, in removing the liquid products of interaction when the seltzogene required to be re-charged, and in preventing the powders evolving gas before the seltzogene could be closed, it must be owned that a very decided advance has been made by the substitution of a sparklet for the purpose of aeration. Moreover, the time occupied in the preparation of an aerated water in the sparklogene is very much shortened, and, in fact, three pints of aerated water may be made ready for consumption in less than five minutes, although, of course, the aeration is very much improved by longer contact of the water with the gas. Three large-sized sparklets are sufficient for the aeration of three pints of water. When the gas is completely discharged from the first sparklet it is taken out after shaking the water and gas together for a few minutes, and replaced by another one, and so on until the contents of three sparklets are discharged. By means of a valve close to the "piercer" the water under pressure is prevented from escaping. When the aeration is completed the sparklet and sparklet-holder are removed and a metal cap put in their place. There is thus no contact of the aerated water with the metal of the sparklet, which at one time gave rise to some of the iron dissolving in the water and communicating to it an inky taste and a turbid appearance. The sparklogene is very convenient for the preparation of aerated mineral waters for medicinal use, such as soda, potash, or lithia water, tablets of the carbonates of these bases being supplied for the purpose. We found the apparatus to work most satisfactorily and the claims made in favour of its advantages are by no means exaggerated. The makers are Aerators, Limited, Upper Edmonton, London, N.

"MORTON'S NEURALGIA."

A CORRESPONDENT writes to us for information as to the treatment of a case of "Morton's neuralgia." This title, otherwise metatarsalgia, is the name given to a painful affection of the foot in which one or more of the digital nerves are pressed upon by the heads of the metatarsal bones. To deal successfully with this condition it is necessary to recognise that the pressure of the metatarsal bones is increased by anything which tends to narrow the anterior part of the foot or to flatten the plantar arch. Therefore boots which are too narrow at the heads of the metatarsal bones should be avoided. In some cases firm bandaging or strapping of the foot at the level of the bases of the metatarsal bones will afford great relief, for this constriction of the bases of the metatarsal bones will tend to separate their heads. In other cases the use of a suitable "vaigus pad" will remove the pain entirely. Care is sometimes required in adopting the vaigus pad to the exact needs of the individual foot but the relief generally obtained is well worth a little trouble. It must not be forgotten that the name of Morton's disease is sometimes applied loosely to any painful affection of the foot.

COMPRESSED SANITARY TOWELS

Messrs Burroughs, Wellcome, and Co. have issued some very convenient compressed sanitary towels for ladies. They are put up in sealed packages and take up but a very small space owing to the great compression to which they have been subjected. They expand thoroughly and well and should prove of benefit to travellers as a large number of them can be carried in a comparatively small space.

M. A. R.—I. We do not think the second call is necessary. 2. We think that further overtures should come from the older residents. There are no hard and fast lines about these matters and our correspondent will probably find that as time goes on through the acquaintances whom he has made he will meet his other colleagues. COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

OPERATIONS

METROPOLITAN HOSPITALS

MONDAY (29th)—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynaecological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopaedic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (3 P.M.).

TUESDAY (30th)—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (2 P.M.), Ophthalmic, 2.15 P.M.).

WEDNESDAY (31st)—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopaedic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Royal Orthopaedic (3 P.M.), Children, Gt. Ormond-street (9.30 A.M., Dental, 2 P.M.).

THURSDAY (1st)—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynaecological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), St. Mark's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Orthopaedic (9 A.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (2.30 P.M.).

FRIDAY (2nd)—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopaedic (2.30 P.M.), Soho-square (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural 2 P.M.).

SATURDAY (3rd)—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9.30 A.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.) and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES

WEDNESDAY (31st)—SOCIETY OF ARTS (John-street, Adelphi, W.C.)—8 P.M. Paper:—Mr T. Adams. The Garden City and the Cottage.

BRITISH BACTERIOLOGICAL AND CLIMATOLOGICAL SOCIETY (20, Hanover-square, W.)—5 P.M. Paper:—Dr A. Morrison. The Present Position of the Treatment of Cardiac Disease by Baths and Exercise.—(If time permits) Dr Braithwaite (Buxton): Cases treated at the Devonshire Hospital by the Buxton Waters.

THURSDAY (1st)—NEUROLOGICAL SOCIETY OF THE UNITED KINGDOM (11, Chandos-street, Cavendish-square, W.)—8.15 P.M. Annual General Meeting. Election of Officers. 8.30 P.M. Paper:—Mr Bateson. Mendelian Heredity and its Application to Man.
NORTH EAST LONDON CLINICAL SOCIETY (Tottenham Hospital, N.)—4 P.M. Dr A. J. Whiting and Dr G. Basil Price. Clinical and Pathological Demonstration (Illustrated by lantern slides).

LECTURES, ADDRESSES, DEMONSTRATIONS, &c

MONDAY (29th)—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.)—4 P.M. Mr G. Fernet: Clinique (Skin). 5.15 P.M. Lecture.—Dr L. Williams. The Therapeutics of Some Common Affections.

POST-GRADUATE COLLEGE (West London Hospital, Hammermith road, W.)—5 P.M. Dr Saunders: Functional Nervous Diseases of Children, with Cases.

TUESDAY (30th)—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.)—4 P.M. Dr R. Abraham: Clinique (Medicine). 5.15 P.M. Lecture.—Dr G. S. Middleton (Glasgow). Remarks on the Diagnosis of Pleural Effusion and of Empyema.

POST-GRADUATE COLLEGE (West London Hospital, Hammermith road, W.)—5 P.M. Mr Dunn. Cancer in its various Forms.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen's-square, Bloomsbury, W.C.)—3.30 P.M. Clinical Lecture.—Dr Batten: Cerebellar Disease.

NORTH EAST LONDON POST-GRADUATE COLLEGE (Colney Hall Asylum, New Southgate, N.)—3.30 P.M. Dr H. Corner: Demonstration on States of Mental Weakness.

WEDNESDAY (31st)—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.)—4 P.M. Mr P. L. Daniel: Clinique (Surgical). 5.15 P.M. Lecture: Dr P. Stewart: Disorders of Articulation.

Three Clinical Lectures

ON

THE "ACUTE ABDOMEN."

*Delivered at St. Thomas's Hospital*By WILLIAM HENRY BATTLE, F.R.C.S. ENG.,
SURGEON TO THE HOSPITAL.LECTURE II.¹*Delivered on Nov. 24th, 1905.*

PATHOLOGICAL PERFORATIONS OF THE DIGESTIVE TRACT.

GENTLEMEN,—In considering the perforations of ulcers of the digestive tract that give rise to the "acute abdomen," it is not proposed to include those which take place at the site of a malignant growth but only those which are known as simple—the sudden giving way of ulcerations of the stomach or bowel into the general peritoneal cavity. It is not my intention to inquire closely into the cause of these ulcerations; this is fully discussed elsewhere and is beside the present question.

GASTRIC ULCERS.

In the autumn of 1894 Mr. A. Pearce Gould² opened a discussion at the annual meeting of the British Medical Association at Bristol on the surgical treatment of simple ulcer of the stomach and duodenum, and typhoid ulceration of the ileum and colon. This debate did a great deal to encourage this branch of surgery in this country and clearly defined the steps of the operation which are essential when any of these ulcers have perforated. There is no doubt that the profession has been much indebted to Mr. Gould for the able manner in which he brought forward this subject, for it did much to encourage operative treatment as a matter of routine. At that time the introducer of the discussion only knew of seven cases of successful operation for the perforation of a gastric ulcer. At the present time the diagnosis and main principles of treatment are so well understood that no surprise is expressed when recovery follows operation. Success is usual and depends more on the individual patient and the time which has elapsed since the perforation took place than on anything else.

In the volume of the St. Thomas's Hospital Reports for 1904 will be found a paper by Mr. P. W. G. Sargent on "Pathological Perforation of the Stomach and Duodenum" founded on 125 cases which have been treated in St. Thomas's Hospital. The series includes seven cases in which perforation complicated carcinomatous ulcer, 20 in which the peritonitis was localised to the neighbourhood of a chronic gastric ulcer, and two in which this limited inflammation complicated chronic duodenal ulcer. This leaves us with 74 perforations of gastric ulcer (four of them acute) and 21 perforations of duodenal ulcer (three of which were acute) in which there was more or less diffuse peritonitis. He reminds us that the first operation for perforation of a gastric ulcer in St. Thomas's Hospital was done in 1892. This was not successful but in August, 1896, a success was obtained for the first time. Altogether, up to the end of 1904 49 cases had been submitted to operation, the ulcer being treated by suture and the peritoneum washed out. 58.1 per cent. of them recovered. The average time in the successful cases that had elapsed between perforation and operation was 23 hours; in the fatal cases 32.6 hours. I am permitted by Mr. Sargent to reproduce an illustration which shows very clearly the position of the ulcer in 77 examples of perforation and you will notice how much more frequent the perforations are on the anterior than on the posterior surface. His series thus confirms the recognised fact as to the greater frequency of perforations on the anterior surface, these being—anterior 66, represented by black dots (the difference is not well marked in the illustration); and posterior 11, represented by circles (see illustration). The results of operation in the second half of the period which he has selected are better than in the first. Cases are recognised and sent into hospital earlier and operation is more quickly and surely performed.

In these cases the symptoms, which are grouped under the word peritonism, are usually very marked and the signs of distress are unmistakable. There is considerable variation as regards the amount of shock; sometimes it is so excessive that nothing can save the patient. Shock is followed by collapse and the patient dies in a few hours without response to medical treatment. Only this autumn a girl was admitted under the care of Dr. H. W. G. Mackenzie with a history of sudden seizure of pain in the region of the stomach so severe that she screamed out and had to be carried home from the tram out of which she had just alighted. When seen at the hospital about an hour later the diagnosis of gastric perforation was confirmed but the

state of shock was so profound that every means to combat this was tried, including saline infusion into the veins, but without success, and the patient died within six hours of the perforation. She was quite unconscious and made no resistance to abdominal examination, nor did she complain of pain. There was a large perforation of about the size of a penny in the anterior wall of the stomach near the pylorus. A curious fact, noted by Dr. W. H. Harnwood-Yarred was the presence of extensive gaseous emphysema of the body a few hours after death.

As a rule the patient rallies from the shock satisfactorily and other symptoms develop, which resemble very much those met with in perforations of other parts of the digestive tract. In gastric and duodenal cases, perhaps more than in others, the previous history is of importance, especially if morphine has been given to relieve the pain. There is nothing like morphine to mask symptoms and many a case has been lost owing to the injudicious administration of the drug in an attempt to relieve the pain at all costs. It is not wrong to give this drug when the diagnosis has been made and the course of action decided upon but there must be no going back because the patient "appears" better. In a large percentage there is vomiting after the perforation but the absence of vomiting is not against the diagnosis of perforation.

Probably there is no form of the acute abdomen in which there is a greater amount of fluid to be found free in the peritoneum; at the operation only a few hours after the accident had happened one has been surprised to find the flanks and pelvis full of a thin greenish fluid, acid and sour-smelling. This statement applies to cases in which the stomach was comparatively empty at the time as well as to those in which the perforation followed a large meal. Much of it is doubtless of a protective character thrown out from the surface of the bowels and omentum in response to the irritation of the acid contents of the stomach. In this respect it resembles very closely the condition which obtains soon after the sudden rupture of the wall of an appendix abscess and the escape of the pus into the peritoneum. Rigidity of the recti muscles in the upper part of the abdomen will be present with great tenderness in the epigastric region.

In any case in which there is a difficulty in diagnosis between a perforated gastric ulcer and an acute diffuse peritonitis secondary to a gangrenous appendix the presence of much free fluid within a few hours after the accident should give a strong leaning towards the stomach as the origin of the symptoms. A tympanitic note over the liver region in an abdomen which is not distended is a very important sign of intestinal perforation and is very commonly observed in gastric perforations soon after the

to that performed by Quenu. In both cases a similar resection of the ulcerated bowel was performed, the jejunal end being placed into the stomach and the duodenal into the side of the jejunum lower down.

The two cases which came under treatment by me were as follows:—

CASE 1.—The patient, a man, aged 30 years, was admitted to City Ward, St. Thomas's Hospital, on July 15th, 1904, for acute abdominal distress. He stated that about four hours before admission he had been seized with violent pain in the abdomen, vomiting, and hiccup. A medical man who was called in sent him to the hospital. On admission the abdomen was moderately distended and did not move on respiration. A rounded prominence was visible in the epigastrium, and immediately below this another and smaller prominence, the latter being situated just above the umbilicus. Distension was most marked in the epigastric and umbilical regions and there was obvious fulness of the flanks. There was no hyperæsthesia of the skin, but considerable, yet not intense, tenderness. No definite tumour could be felt. The resonance was impaired in both flanks, but no fluid thrill could be felt nor was the dullness a shifting one. Elsewhere the note was of a tympanitic character, this being especially marked in the epigastric region. The liver dullness was entirely obliterated, the note over the region of the liver being decidedly tympanitic. The general condition of the patient was good. The temperature was 98° F., the pulse was 100, and the respirations were 20.

The presence of a scar in the abdominal wall caused questions to be asked about previous operation and the following history was obtained, some of which was subsequently verified. He had suffered from indigestion after he became 16 years old and three years ago he was much troubled with vomiting from a quarter of an hour to two hours after food and on one or two occasions he brought up blood. 22 months previously he underwent an operation in Queen's Hospital, Birmingham, for pyloric obstruction after gastric ulcer. Anterior gastro-enterostomy was performed, a Murphy's button being used to approximate the parts. His progress after this operation was uninteruptedly good until March 4th, 1904, when he was seized with pain in the abdomen and he had to go into the hospital again for "obstruction"; at this operation the Murphy's button was removed.

An incision was made immediately to the right of the middle line above the umbilicus through the rectus sheath, the muscle being temporarily displaced outwards. There was a rush of gas when the peritoneum was opened and a greatly distended coil of bowel presented below the wound; this was punctured and emptied of much gas. The opening was closed with Lambert silk sutures and the coil was returned. The stomach, which was much distended, was drawn into the wound; the point of attachment of the small intestine to the gastric wall was defined and a small round perforating ulcer, about a sixth of an inch in diameter, was located in the anterior part of the jejunum at a distance one and a quarter inches from the point of attachment of the latter to the stomach. The stomach and the upper part of the jejunum were as far as possible emptied of gas through the ulcer and this was then turned in with a single row of Lambert's sutures. The coils of jejunum in the immediate neighbourhood of the perforation were greatly distended, thickened, and of a dull red colour. A small amount of free purulent fluid was present in the abdominal cavity with patches of lymph on the intestinal coils. A second incision was made in the middle line above the pubes and the peritoneal cavity was thoroughly irrigated with normal saline solution. A Keith's drainage-tube was then inserted into the privis through the lower incision and the upper wound was closed. The man's general condition at the end of the operation was good.

There is not much to record in the after progress of the case. The patient was sick three times during the night following the operation, bringing up each time large quantities of greenish fluid. In the morning a turpentine enema was administered with a very good result. Sulphate of magnesia (two teaspoonfuls) was given every four hours. The abdomen was very slightly distended and not very tender; it moved to some extent with respiration, though not freely. The pulse was 104 and the respirations were 20. The bowels acted again on the following day, the abdominal distension subsided, the man became much more comfortable, and towards night the sickness ceased. The Keith's tube was replaced by a rubber one of smaller size, there

being very little discharge. Two days later this was removed altogether. He left the hospital on August 8th, having completely recovered.

The second case was very similar but the symptoms were much less acute at the onset. The previous history was a very interesting one.

CASE 2.—The patient, an unmarried woman, aged 37 years, was sent to the hospital by Mr. J. Scott Battams and admitted under the care of Dr. Mackenzie on March 25th, 1903, with symptoms of perforated gastric ulcer, which had commenced four and a half hours before. Operation was performed by me at 11.15 P.M. and an ulcer near the pylorus and on the anterior surface was found and sutured, the peritoneal cavity was washed out, and the pelvis was drained. At the operation it was noted that there was a good deal of cicatricial narrowing of the pylorus. She left hospital on May 12th and continued well until October, after which her gastric pains recurred. She was re-admitted in April, 1904, and anterior gastro-jejunostomy was performed. The stomach was dilated, the lower border reaching the level of the umbilicus. The pylorus was much strictured. The operation was on the 8th and she left hospital on April 28th.

The patient appears to have done very well afterwards and regarded herself as cured until May, 1905, when she was again sent to the hospital by Mr. Battams. About six hours before admission on May 5th she had a severe attack of pain, especially in the right side of the abdomen, with vomiting. The bowels had acted twice on that day. When examined in the ward the abdomen did not appear to be distended and moved freely in respiration. The liver dullness was normal and there was normal resonance in other parts. The pulse was 72; it was good and strong. The temperature was normal. There was, however, slight tenderness all over the abdomen with more evident tenderness above, and to the left of, the umbilicus. She vomited two or three times during the night; on the morning of the 6th the temperature had been up to 99.4° F. and a distended coil of small intestine was seen above, and to the left of, the umbilicus. There was tenderness as before but it was more marked over the distended coil. When seen by me at 2 P.M. the condition was much as above described but the distension of the small intestine in the umbilical region was greater and there was visible peristalsis.

Operation was performed 23 hours after the first onset of pain, the abdomen being opened through the left rectus sheath about an inch from the middle line. A red and distended coil of small intestine presented which traced upwards led to the old gastro-enterostomy junction; from this a greatly distended coil passed downwards, on the anterior aspect of which, one and a half inches from the line of junction, was a somewhat rounded opening from which gas and intestinal contents were escaping. The coils near were much thickened, cedematous, and distended, there being lymph on the surfaces near the perforation. A knife was introduced through the ulcer and a cut was made upwards, so that the line of junction between the stomach and intestine could be explored; the finger passed easily into the stomach and then into the jejunum beyond the line of junction. There had been no contraction of the openings. The continuous silk suture which had been employed to unite all the coats of the stomach and intestine was felt lying partly detached, and removed. It was apparently unaffected by the action of the gastric juice. After the distended coils had been emptied, the incision was closed with silk Lambert sutures, and the intestines were washed with sterilised saline solution. A second incision was now made in the middle line above the pubes through the old scar and the pelvis was emptied of a small amount of purulent fluid which was not of offensive odour. It was well cleansed with sterilised saline solution and both wounds were then sutured without drainage. Shock was counteracted by the administration of half a pint of saline solution per rectum every two hours. The patient soon rallied from the shock and complained of no pain. Progress was satisfactory until May 11th when she vomited once. She vomited several times on the 18th, and again on the 17th, and on this date the pulse was quick and feeble. A suggestion was made that there was obstruction of the opening of gastro-enterostomy, but this had already been found to be in a satisfactory condition. Her temperature was normal, the abdomen moved well and was without distension. Rectal feeling and washing out of the stomach sufficed and no vomiting occurred after May 20th, when she was allowed to

sudden onset of pain. Its absence must not, however, be regarded as a reason for postponing operation in a case otherwise calling for it. It was not present in the following instance of severe perforation in which the accident occurred although the patient was under exceptionally advantageous conditions, the stomach having had rest for two days.

A man, aged 48 years, was admitted under the care of Dr. Mackenzie on Sept. 30th, 1904, with symptoms of gastric ulcer. The history of the case was that he had been often sick in 1902 and 1903. Vomiting occurred about half an hour after food and the vomited material was very acid. In January, 1904, he vomited a large amount of blood which was very black; this vomiting recurred a few days after. In July he had a similar attack of hæmatemesis. When admitted he was suffering a good deal from pain in the epigastric region and was obliged to lie on the left side. The abdomen was normal in appearance and with the exception of tenderness in the epigastrium was without evidence of disease. He was unable to keep down milk sometimes. In the next few days he complained at times of severe local pain and hot fomentations were required for his relief. Vomiting also occurred at intervals. On Oct. 22nd it was decided to put him on rectal feeding and to give nothing by the mouth. At 2 A.M. on the 24th he had a severe attack of pain, perspired very freely, and his pulse rose to 120. When seen with Dr. Mackenzie 12 hours later he was evidently suffering acutely. Lying on his back with head and shoulders raised, he looked pale, agitated, and intensely anxious, whilst his face and forehead were covered with sweat. His respirations were hurried, painful, shallow, and irregular, the pulse was rapid, and he complained much of pain in the abdomen. He was unable to take a deep breath on account of the pain, and on examination of the abdomen it did not move much with respiration. It was generally tender, rigid, and rather distended. The liver dulness had not disappeared; there was dulness in both flanks and also across the lower abdomen above the pubes. He had vomited. The temperature was 100.6° F.

Operation was performed as soon as possible. On opening the peritoneum there was a flow of greenish thin, sour-smelling fluid. The stomach was somewhat adherent to the under surface of the liver and when they were separated by the finger there was a gush of free gas. The finger was passed to the pyloric region at once because of the diagnosis of perforation of ulcer in that situation made out by Dr. Mackenzie. A sharply cut ulcer, large enough to admit the forefinger, was found on the anterior surface of the pyloric end of the stomach. The stomach wall round this perforation was much thickened. The opening of the ulcer was closed. The peritoneal cavity appeared to be filled with the greenish fluid, there being large collections in the pelvis, the flanks and the sub-hepatic and splenic regions. A counter opening was made above the pubes and the whole abdomen was thoroughly irrigated with normal saline solution. The intestines were not much distended. The deposit of lymph was limited to the parts around the perforation. Normal saline solution to the amount of two pints was passed into the median basilic vein during the operation as the pulse became very feeble and rapid. The stomach was a good deal dilated. The upper wound was closed and a glass drain was placed in the lower one. Recovery was slow but satisfactory and he left on Dec. 7th for his home in the country. From recent accounts it is probable that he is now suffering from pyloric obstruction and dilated stomach; indeed, it would be very strange if he escaped this complication, for the nature of the ulcer compelled the infolding of an unusual amount of stomach wall.

PERFORATIONS OF DUODENAL ULCERS.

These ulcers are far less frequently met with than the gastric and it is not always possible to diagnose the one from the other. They are far more common in males. Osler³ says that they may be distinguished by the following definite characters: "(a) Sudden intestinal hæmorrhage in an apparently healthy person which tends to recur and produce a profound anemia. Hæmorrhage from the stomach may precede or accompany the melæna. (b) Pain in the right hypochondriac region, coming on two or three hours after eating. (c) Gastric crises of extreme violence during which the hæmorrhage is more apt to occur. Certainly the occurrence of sudden, intestinal hæmorrhage with gastralgi-

attacks is extremely suggestive of duodenal ulcer." Unfortunately, in many cases there is no history of local pain preceding the acute attack.

From the surgeon's point of view these cases are especially interesting because it is frequently very difficult to distinguish perforations of these ulcers from acute disease of the appendix with peritonitis, especially if the appendix is situated to the outer side of the cæcum or has never attained its proper position in the iliac region. "When the ulcer is in the stomach the signs are those of a general peritoneal involvement; when the ulcer is duodenal the course taken by the extravasated fluids leads to a more acute and earlier involvement of the peritoneum on the right side and in the right iliac fossa. The clinical picture of appendicitis is expressed with such accuracy that of 49 recorded cases, in 18 the first incision was made over the appendix after a diagnosis of acute appendicitis had been made." At the time of operation the appendix may be found surrounded by an area of inflamed peritoneum and may be itself so inflamed that the surgeon is misled. It would be well, therefore, to examine the duodenum in its first part when the apparent disease of the appendix is not manifested by gross naked eye change, such as gangrene or perforation.

SIMPLE ULCER OF THE JEJUNUM.

The knowledge that an ulceration of the jejunum is one of the forms of disease of the small intestine which must be considered by the surgeon in the present day was due in the first place to Braun. In 1899 he met with a case in which an ulcer of that part perforated and produced a fatal peritonitis. This ulcer produced symptoms a year after the operation of posterior gastro-enterostomy. Since that time there have been recorded 16 cases in which ulceration of the jejunum has required surgical treatment. In all these there had been a previous operation performed, that of gastro-enterostomy, for the relief of some non-malignant disease of the stomach. To these must be added two more, making a total of 19. I have purposely refrained from using the term "peptic" as applied to these ulcers, for it is not proven that they are all, or any of them, due to the hyperacidity of the gastric juice; indeed, in more than one the state of the gastric juice is described as normal. The appearance of these perforations in the two cases here described was certainly similar to that of some perforated gastric ulcers and perforated duodenal ulcers. They also resembled the ulcers in two cases of perforation of the ileum during the course of typhoid fever, on which operation was (successfully) performed at the request of Dr. Mackenzie; the naked-eye appearances were quite similar. They are probably due to an acute bacterial invasion but I do not think the term "peptic" should be used. It is an interesting fact, however, that they are only met with after the operation of gastro-enterostomy and chiefly after anterior gastro-enterostomy—for example, out of the 19 cases two followed posterior gastro-enterostomy, one the Y operation of Roux, while the particular operation is not given in the account of one case, and no less than 15 followed anterior gastro-enterostomy.

The most fatal complication of jejunal ulcer is acute perforation and in this, as in the other complications, it resembles other simple ulcers of the digestive tract. This occurred in eight instances from ten days to 13 months after gastro-enterostomy. Operation was successful in saving three of them—one treated by Dr. Goepel and two now recorded. A more gradual perforation, with the formation of a localised abscess, was a much less serious occurrence, for in six instances operation was followed by recovery, whilst in a seventh fistula resulted. A successful result also followed in three cases where the progress of the ulceration was more chronic and adhesions of the base to the parts beneath had taken place. The amount of thickening about one of these chronic ulcers and its involvement of surrounding tissues may be extensive.

In a case recorded by Quénn the symptoms of ulcer came on four years after gastro-enterostomy, and at the operation extensive ulceration had passed beyond the bowel into the abdominal wall, its extent being limited by adhesions. In a case under the care of Mr. A. W. Mayo Robson the symptoms were severe and distressing and the local signs were definite, whilst the extent of bowel involved required an extensive operation for the removal of the disease similar

³ Diseases of the Stomach, Mayo Robson, p. 336.

to every medical man. This point of view is the more necessary in the present series, since the notes of the cases were made from a clinical aspect, anatomical and pathological description being conspicuous by its absence. Therefore, leaving out the question of etiology and briefly alluding to a few general facts concerning the cases, attention will be directed to the diagnosis and prognosis, but especially to the treatment, of this condition.

General facts.—In this collection there are 94 cases, of which six mothers died, or 6·3 per cent., whilst of 93 infants 49 died, or 52 per cent. As regards parity, of the 78 cases in which it is mentioned 12 were primiparae whilst 23 had had five labours or more previously. None of the primiparae died, which is a matter of some interest, since King in his series found the mortality of primiparae to be 30 per cent., the general mortality in his collection being 22 per cent. Twin labours occurred twice in the series, of which three infants and one mother died. Recurrence in one case is noted in the three preceding labours. Hydranmios was reported in four cases, two of these being of the ten cases seen personally. Prolapse of the cord happened in three cases out of 54 in which the de Ribes bag was not used and in four cases out of 40 in which it was used. Post-partum flooding was noted in 14 cases, in four of which the placenta was adherent; adherence of the placenta was found in two other cases without post-partum hæmorrhage. There seems to be a peculiar tendency for a placenta with a low implantation to become adherent. In two cases of post-partum hæmorrhage there was atony of the uterus; both died. One case of puerperal melancholia is recorded.

Diagnosis.—Since an early diagnosis is an essential feature in the successful treatment of placenta prævia it is clear that any means of detecting this condition before the os uteri will admit the finger is of great service. Levret more than a century ago noticed that in some cases of placenta prævia the uterus as felt through the abdomen consisted of two parts, the smaller corresponding to the placenta. Spencer, in 1859, was the first to lay especial stress on palpation of the placenta through the abdominal wall as a means of detecting placenta prævia. In Case 62 a doughy mass was felt in the abdomen below the fœtus which was suspected to be placenta; examination per vaginam showed this to be the case, the os here admitting the finger. In Case 2 an indefinite mass was felt in the lower part of the abdomen, also through the vagina; this mass could be felt between the head of the fœtus and the examining finger in the fornix; the os in this case did not admit a finger. After some deliberation this was judged to be placenta and the os was dilated; the placenta was partially prævia. It is necessary that the abdomen should be fairly thin to feel the placenta through it with any degree of certainty. It is interesting to note that flooding may occur from a low implantation of the placenta which may not be perceptible to the fingers until they penetrate a considerable way inside the os uteri. Cases 5 and 61 are examples of this; in both, to judge by the amount of clot which was expelled with the placenta, the hæmorrhage was at first concealed, the flow of blood having stripped the membranes from the uterus until the os uteri was reached when the flooding became manifest externally. Cases 4 and 61 contrast well, since in the former there was no flooding but only early rupture of the membranes, slow labour, and prolapsed cord; the latter, with a very similar position of the placenta, suffered from a great flooding. The severity of the hæmorrhage by no means depends in all cases on the position of the placenta.

Differential diagnosis.—As has been already pointed out, abdominal palpation and bimanual examination before the os admits a finger may prove of great service in the distinction between flooding due to low implantation of the placenta, or unavoidable hæmorrhage, and that occurring when the placenta is situated above that zone, or accidental hæmorrhage. In a stout patient, however, it is necessary to introduce a whole hand into the vagina and a finger into the uterus before the presence or absence of placenta on the lower zone can be ascertained. In a case of rupture of the uterus, the history of labour advancing to the second stage without flooding, the sudden hæmorrhage and disproportionate collapse of the patient, and a bimanual examination revealing recession of the presenting part and probably the fœtus and uterus lying separate to some extent should make the condition fairly clear. At the same time it may be remembered that cases of ruptured uterus complicating placenta prævia have been reported.

As regards flooding from the lower part of the genital

canal—that is to say, cervix, vagina, and vulva, the possible history of injury, the presence of a wound, a growth, or varicose veins will aid in diagnosis. Still, flooding may occur so violently as to endanger life in a few moments and so rapidly as to leave but little time for diagnosis. For this reason I record Case A, in which the flooding and collapse were so sudden that the source of hæmorrhage was not exactly ascertained, though I strongly suspect it to have come from a ruptured varicose vein in the vagina. In this case means were taken to exert pressure on any bleeding point there might be in the genital canal from the upper end of the lower uterine segment down to the vulva.

Prognosis.—The most important factor in the prognosis of these cases is the treatment adopted. This is shown by the great lowering of the death-rate following on a proper appreciation of the causes of bleeding and the adoption of rational means of stopping it—namely, by direct pressure on the bleeding point: an advance which is associated with the names of Legroux, Barnes, Braxton Hicks, Hofmeier, Behm, and others who have adopted their principles and methods. There remain, however, certain conditions outside the power of the medical attendant which influence the prognosis. The maternal death-rate rises with the prolongation of pregnancy. 62 labours occurred in the various months of pregnancy in the following proportion.—Seven months, 9; eight months, 19; nine months, 17; and term, 17: the percentage mortality of mothers and infants being:—seven months—mothers 0 per cent., infants 100 per cent.; eight months—mothers 10 per cent., infants 68 per cent.; nine months—mothers 6 per cent., infants 47 per cent.; and term—mothers 18 per cent., infants 41 per cent.; showing that a prolongation of pregnancy to the last month more than doubles the danger to the mother while the infant mortality is reduced by one-third, a sufficient reason for inducing labour as soon as a diagnosis is made.

The extent to which the placenta encroaches on the lower uterine segment is likewise of moment in the prognosis; of 85 cases the placental insertion and maternal deaths were as follows: Central 15, mothers died 4; partial 25, mothers died 1; marginal 35, mothers died 0; and lateral 9, mothers died 0. That is to say, the mortality in complete placenta prævia was over 25 per cent., in partial cases, 4 per cent., and in lateral and marginal, 0.

A third and very important factor in prognosis is the condition of the patient when treatment is commenced with regard to (1) anaemia and collapse, and (2) stage to which labour is advanced, the former depending largely on the latter, as is clear from the following considerations. In 45 cases the os uteri would admit three fingers or less; only two of these died, in one of which the os was dilated manually for two hours. In six cases the os was from half to fully dilated, of these two died; moreover, in the two remaining cases which died and in which the size of the os is not stated it is related that a leg was brought down, from which it is probable that some considerable dilatation of the os was present. This shows the prime importance of early diagnosis and treatment, since it is manifest that those cases did worst which were farthest advanced in labour when treatment was undertaken, in consequence doubtless of the greater amount of flooding and collapse which occurred before help arrived.

TREATMENT AND RESULTS.

The cases are divided into four groups, according to the variety of treatment used. I begin at the end of the series, leaving for fuller consideration the cases in which the de Ribes bag was used.

Group D.—This series of 27 cases consists of those in which no treatment or only such minor steps as rupturing the membranes or giving ergot were taken. The cases were mostly of a mild nature, there being no case of complete placenta prævia in the set; two cases were certainly severe, the pulse-rate in one being 140. None of the mothers died. Only six infants, or 22 per cent., died. There were five cases of post-partum hæmorrhage, two of which were considerable. There are then a certain number of cases in which treatment, except of the slightest, is not necessary; such cases, however, need watching, for there is always a chance of flooding till labour is complete. To use no treatment, or such apologies for treatment as the injection of styptics as a routine, leads to disaster. King records in his series 33 such cases, of which 11—i.e., 33 per cent.—died.

Group C.—In six cases bipolar version was the treatment

take milk in small amounts. On June 1st she was taking ordinary diet. She left the hospital on June 2nd and has continued well since, showing no tendency to weakness of the various scars.

There are various points in these cases which are worth attention. 1. In both the ulcers gave no intimation of their presence until perforation occurred. 2. The symptoms were very much like those resulting from an obstruction by a band, there being well marked localised distension and peristalsis of the bowel near the perforation. 3. The distension of the bowel when exposed was found to be very great, but it could be relieved by forcing the contained gas through the perforation, after which manipulation was easy. In the first case it was not so easy to find the perforation. 4. In neither case was it necessary to excise the ulcer which was of limited extent and without much thickening of the edges. 5. In both a counter opening was required for satisfactory cleansing of the pelvis, but both wounds were closed, without drainage in the second case. The proportion of recorded cases of simple ulcer of the jejunum to the cases of gastro-enterostomy appears to be much against the anterior method of operation, but this tells as an argument less forcibly than would appear because it is very probable that the anterior operation has been performed much more frequently than the posterior. The anterior operation, moreover, possesses advantages which are likely to make it the more favoured operation of the future. The danger of the formation of this kind of ulcer is so slight that it may be neglected in considering the question.

PERFORATIONS OF THE SMALL INTESTINE MET WITH DURING THE COURSE OF AN ATTACK OF TYPHOID FEVER.

This group differs from the others which we have been considering inasmuch as the "acute abdomen" develops during the course of an illness which may have already severely tried the strength and endurance of the patient. It has been calculated by Dr. Mackenzie¹ that 3.3 per cent. of all cases of typhoid fever die from this complication; and further, that 69.6 per cent. of them occur during the second, third, or fourth week of the illness. His lecture is so very interesting and instructive that you cannot do better than read it for yourselves. Peritonism, the result of a perforation of the ileum, is often not very marked, and unless some such series of rules as those suggested for the nurse by Professor W. Osler² in cases of typhoid fever be enforced the occurrence may be overlooked. As a rule these patients are under skilled observation, therefore there is a chance for them which is not afforded the majority of those in our other groups. They are watched from the beginning and every preparation is made for operation at the earliest moment. Then, again, the contents of the ileum in this disease are frequently scanty and the perforation may not admit of the escape of much fluid; at all events the sensitive peritoneum is not flooded at once with a highly irritating acid compound, the amount of which rapidly increases from minute to minute.

About this time last year (November, 1904) a man, aged 30 years, was under treatment for suppurative periostitis of the femur and when the pus was evacuated a bacteriological investigation showed the presence of many typhoid bacilli in it. When he left the hospital the wound had closed. The history of this patient was briefly as follows. At the request of Dr. Mackenzie operation was performed on July 11th, 1902, five and a half hours after the commencement of symptoms indicating perforation. There had been sudden pain in the umbilical and right iliac regions, soon followed by vomiting. There were before operation the following local signs: resistance and tenderness in the umbilical and right iliac regions with deficiency in movement of the lower abdomen. The liver dulness was normal. There was no evidence of free fluid. The pulse was 104 and the temperature was 101° F. The amount of shock was slight. Incision below the umbilicus showed a round, clean-edged perforation about a quarter of an inch in diameter. There were some yellowish feculent fluid around the perforation and a small amount of lymph. The patient made a satisfactory recovery from the effects of the perforation but returned later for pain in the thigh which subsided under appropriate treatment. He was able to return to his work as a coal-heaver in the following year and continued to do it until the attack of

periostitis to which I have alluded. I may mention here as a curious addition to this history that the wound reopened after he left the hospital and as recently as December, 1904, the pus contained typhoid bacilli on bacteriological examination.

A second patient was also under the care of Dr. Mackenzie and symptoms of perforation had been noted 12 hours before operation on Dec. 4th, 1901. He was a man, aged 22 years, and the complication developed during a relapse. At the time of operation there were pain, distension, shifting dullness, indicating fluid in the flanks, extreme tenderness in the right iliac fossa, and a complete absence of dullness in the liver region. The pulse was 94, the respirations were 26, and temperature was 102.4° F. This temperature fell rapidly to 97° after operation, but soon rose again. Incision below the umbilicus showed a similar condition to that in the previous case, yellowish fluid, a coil of ileum to which a tag of omentum was adherent, and when this was lifted up a sharply cut circular ulcer measuring about one-eighth of an inch across was seen below it. Suture of the ulcer and cleansing of the peritoneum sufficed to prevent further local mischief and the patient recovered.

I have mentioned the subject of typhoid ulceration, of which I was reminded by the readmission of the man whose case I have first recorded when some of the other patients with perforations of the digestive tract were in the ward, because I especially wish to draw attention to the character of these perforating ulcers. They were no different from those which I have mentioned as occurring in other parts of the digestive tract; the perforation was that of an ulcer far removed from the influence of the gastric juice but possessing appearances which were quite indistinguishable from them. We cannot call them "peptic" and I can but think that too much importance is attached to the effect of the gastric juice on the jejunal ulcers which very rarely follow the operation of gastro-enterostomy. These ulcerations are very different from the typical typhoid patch with its thinned base and the prognosis is, of course, very much better, for the wall of the bowel near to the perforation is quite firm and will hold a stitch. In fact, in the second case the edges were drawn together with a No. 1 silk suture to prevent further escape of contents before Lembert's sutures were inserted. The amount of the shock was not severe in either patient. The rate of the pulse in the first was increased in frequency from 68 to 84, 45 minutes after the time of the perforation and to 104 three hours after. In the second it was more constant at 95 from two hours to ten hours after the time of the perforation. Patients with typhoid fever often suffer from abdominal pain. This has been so severe that abdominal exploration has been performed a number of times without anything having been found to account for the pain. The principal symptoms to trust to are, locally, pain and tenderness with rigidity of muscles and a fixity of the lower abdomen during respiration. If the liver dulness is absent the sign is important. In one of these cases there was no change in this respect even at the end of five and three-quarter hours after perforation.

PLACENTA PRÆVIA: A SERIES OF 94 CASES.

BY RICHARD WARREN, M.A., M.D. OXON.,
F.R.C.S. (ENG.).

LATE RESIDENT ACCOUCHEUR AT THE LONDON HOSPITAL.

THE patients forming this series were all treated either in the London Hospital or in their own homes by the London Hospital Maternity Charity in the years 1894-1904. Ten of the cases were attended personally. Seeing that the patients have been under the care of some fifteen or twenty different resident accoucheurs they may be expected to show an average result of the treatment of placenta prævia by modern methods, particularly by the use of a de Ribes bag. I wish to thank Dr. A. H. N. Lewers and Dr. H. R. Andrews for leave to publish these cases.

In discussing placenta prævia the main interest centres in the treatment, which consists in the methods of dealing with one variety of acute hemorrhage, a subject which appeals

TABLE GIVING PARTICULARS OF 94 CASES OF PLACENTA PRÆVIA—(Continued).

GROUP A.—Cases Treated by Means of the Champetier de Ribes Bag—(Continued).

No. of case.	Age.	Previous pregnancies.	Months pregnant.	State of labour and of patient.	History.	Treatment.	Result.	
							Mother.	Child.
36	30	3	—	—	—	Bag; version.	Recovery; normal.	Alive.
37	30	9	—	—	Great ante-partum flooding.	Bag; forceps.	" "	Dead.
38	36	7	—	—	—	Bag; ergot.	" "	"
39	40	11	—	—	—	Bag; natural delivery.	" "	"
40	29	1	—	—	Ante-partum flooding.	Bag; version; post-partum flooding.	" "	"

GROUP B.—Cases Treated by Version or Manual Extraction in Breech Presentations.

41	27	4	8	Os uteri admits hand; pulse over 140; pale; collapsed.	Flooding 14 days.	Placenta separated; leg brought down.	Death in three weeks; septicæmia.	Alive.
42	27	—	7	—	—	Leg brought down.	Died suddenly.	Died.
43	44	17	6½	Os uteri one finger; pulse rapid; collapsed.	Flooding two days.	Manual extraction after bringing down leg.	Recovery; normal.	"
44	35	9	4½	Os uteri two fingers.	—	Fœtus extracted manually.	Recovery; sapræmia.	"
45	26	3	8	Os uteri crown piece; pulse 150; blanched.	Flooding during labour.	Internal version after failure of forceps.	Recovery; normal.	Alive.
46	39	12	9	—	A flooding at 5 months.	Leg brought down; bad post-partum flooding; atonic uterus.	Died in 4 hours.	Died.
47	28	1	6	Os uteri three fingers; pulse 120; blanched.	Flooding 1 day badly.	Leg brought down.	Recovery; septicæmia.	"
48	30	5	9	Os fully dilated.	Flooding 14 days.	Version.	Recovery; normal.	Alive.
49	26	1	8½	Os uteri two fingers; anæmic.	Flooding 4 months.	Internal version.	" "	Died.
50	26	—	—	—	Ante-partum hæmorrhage.	Version.	" "	"
51	24	—	—	Os three-quarters dilated.	Lossing 14 days.	"	" "	Alive.
52	32	8	—	Good condition.	Hæmorrhage few days.	"	" "	"
53	28	1	—	Kyphotic pelvis.	—	"	" "	Died.
54	34	9	—	—	—	Leg brought down.	" "	"
55	27	3	9	—	—	Version.	" "	Alive.
56	33	4	9	Os uteri two fingers.	Ante-partum flooding.	Os dilated manually; version. Post-partum flooding; atonic uterus.	Death, shortly.	Died.
57	42	12	—	—	Great ante-partum flooding.	Version.	Recovery; normal.	Alive.
58	18	1	8	—	—	Os dilated; version.	" "	Died.
59	24	2	—	—	—	Version.	" "	Alive.
60	36	5	—	—	—	"	" "	Died.
76	35	—	7	Os fully dilated; pulse 144; collapsed.	Flooding 3 days; twins.	Twins; version.	Died in 13 hours.	2 died.

GROUP C.—Cases Treated by Bipolar Version.

61	39	5	6	Os uteri three fingers; pulse 120; pale.	Flooding a few hours.	Bipolar version; ergot; later, post-partum flooding.	Recovery; normal.	Died.
62	34	7	7	Os uteri two fingers; pulse 105; pale.	Flooding 3 days.	Bipolar version; ergot.	" "	"
63	25	3	6	Os uteri one finger; good condition.	" "	" " "	" "	"
64	44	13	7	Os uteri one finger; rapid pulse.	Lossing 3 months.	Bipolar version; ergot; post-partum hæmorrhage.	Recovery after hysterectomy 7 weeks later for continued flooding.	Alive.
65	29	2	9	Os uteri two fingers.	Lossing 5 weeks.	Bipolar version.	Recovery; normal.	Died.
66	—	9	—	—	Flooding weeks before admission; temperature 101° F.	Bipolar version; rigor next day and diarrhœa; death in 2 days.	Death; septicæmia.	(?)

GROUP D.—Cases not Treated or in which only Minor Treatment was used.

67	21	1	5	Os uteri two fingers; pulse 90; good condition.	Bleeding 12 hours.	Nil; spontaneous delivery.	Recovery; normal.	Dead.
68	24	0	9	Os uteri half dilated; pulse 100; fair condition.	Flooding 24 hours; hydramnios.	Membranes ruptured; forceps.	" "	Alive.
69	37	8	8	Os uteri crown piece; pulse 140; anæmic.	Flooding 6 weeks.	Membranes ruptured.	" "	"
70	29	9	5½	—	Irregular losing.	Ergot; membranes ruptured.	" "	Dead.
71	25	2	8	Os uteri one finger.	Flooding 6 weeks.	"	Recovery and bronchitis.	Alive.

TABLE GIVING PARTICULARS OF 94 CASES OF PLACENTA PRÆVIA.
GROUP A.—Cases Treated by Means of the Champetier de Ribes Bag.

No. of case.	Age.	Previous pregnancies.	Months pregnant.	State of labour and of patient.	History.	Treatment.	Result.	
							Mother.	Child.
1	21	0	7	Os uteri three fingers; pulse 120; pale.	Two or three floodings last 14 days.	Bag inserted alongside placenta; version.	Recovery; normal.	Alive; died in 8 hours.
2	30	4	6	Os uteri half a finger; pulse 120; pale.	Intermittent flooding 2 months.	Ergot 5 days; Hegar's dilators; bag; manual extraction.	Recovery; slight pyrexia.	Alive; died in 24 hours.
3	21	0	9	Os uteri three fingers; pulse 90; good condition.	A flooding 14 days before.	Bag inserted alongside placenta; version.	Recovery; normal.	Alive; died well.
4	36	0	7½	Os uteri one finger; kyphoscoliotic pelvis; good condition.	Flooding a few hours; hydramnios.	Bag; forceps.	" "	Died.
5	40	12	9	Os uteri three fingers; good condition.	Membranes ruptured 48 hours before; cord down.	Bipolar version failed; bag; child transverse; decapitated.	" "	"
6	33	9	9	Os uteri one finger; good condition; pulse 88.	Bleeding on day that labour began.	Bag inserted through membranes; ergot; forceps.	" "	"
7	41	7	9	Os uteri one finger; good condition.	Flooding 10 and 4 days before.	Bag; ergot; cord prolapsed; version.	" "	Alive.
8	33	5	8	Os uteri one finger; pulse 120-140; anæmic.	Flooding 1 day.	Bag inserted alongside placenta; version.	" "	Died.
9	36	6	8	Os uteri two fingers; pulse 80; very anæmic.	Flooding 2 months; great flooding recently.	Bag; natural delivery.	" "	Alive.
10	34	8	7	Os uteri two fingers; pulse 90.	Flooding 14 and 2 days before.	Bag inserted through placenta; ergot; delivery.	" "	Died.
11	26	*	9	—	—	Bag.	Recovery with slight aspræmia.	Alive.
12	20	0	8	Os uteri one finger.	Flooding 14 days before.	Bag; cord prolapsed; ergot.	Recovery; albuminuria.	"
13	35	6	9	Anæmic.	Flooding 3 days.	Bag; prolapse of cord; version.	Recovery; normal.	Died.
14	21	2	7½	Os uteri two fingers; pulse 85.	Flooding a week before.	Bag; ergot.	" "	Alive.
15	32	5	7	Os uteri undilated.	Labour induced for small round pelvis.	Bag; external version.	Recovery.	Alive; died.
16	42	7	8	Os uteri two fingers.	Losing 5 weeks.	Bag inserted in front of placenta; prolapse of cord; forceps.	Recovery; normal.	Alive.
17	30	3	7½	—	Flooding 14 days.	Bag and weight extension; version.	" "	"
18	29	3	9	Pulse 144.	Labour induced for small pelvis.	Bag; internal version.	" "	"
19	34	0	6	Os uteri one finger; pulse 120.	Flooding 8 days.	Bag; ergot.	Recovery; with aspræmia.	Died.
20	35	11	7	Os uteri three fingers.	Bleeding 1 day. Last three labours were placenta prævia.	Bag; transverse; dead; decapitation.	Recovery; normal.	Dead.
21	29	3	8	Good condition.	Losing 3 days.	Bag; version.	Recovery with melancholia.	Alive.
22	37	7	8½	Os uteri two fingers; pulse 140; anæmic.	Bleeding 23, 14, and 3 days before.	Bag; version.	Recovery with slight sepsis.	Dead.
23	37	10	8	Os uteri two fingers; pulse 103.	Bleeding at intervals 1 month.	Bag; ergot; version.	Recovery after 6 weeks; parametritis, &c.	"
24	42	11	9	Os uteri two fingers; blanched.	Flooding 3 months, 1 month, and 3 days before.	Bag through placenta; version; post-partum hæmorrhage.	Recovery; pyrexia 14 days.	Alive.
25	32	2	—	Os uteri two fingers; anæmic.	Hæmorrhage some months.	Bag; external version.	Recovery; slight aspræmia.	Dead.
26	23	0	9	Os uteri one finger; blanched.	Flooding 6 days.	Bag; ergot; forceps.	Recovery; normal.	"
27	33	12	7	Os uteri one finger; anæmic.	Hæmorrhage 2 days.	Bag; natural delivery.	" "	"
28	34	0	9	Os uteri two fingers.	Hæmorrhage 4 days.	Bag; forceps.	Recovery and pyrexia 1 week.	Alive.
29	37	6	9	—	Losing 3 months.	Bag; natural delivery.	Recovery; normal.	Dead.
30	37	—	—	Pulse 120.	Twins; first born naturally.	Bag after first child; version.	Recovery and pyrexia 1 week.	Two dead.
31	—	9	7½	—	Hæmorrhage 2 days.	Bag; version.	Recovery after pneumonia.	Dead.
32	28	5	8	Os uteri three fingers.	Three floodings in last week.	Bag; natural delivery.	Recovery and pyrexia 5 days.	"
33	33	6	8	Os uteri one finger; pulse 120; pale.	Flooding 1 month.	Bag; ergot; manual extraction.	Recovery; normal.	"
34	33	8	7	—	Hæmorrhage 1 month.	Bag through placenta.	"	"
35	22	0	9	Os uteri admits one finger.	Labour began without flooding.	Bag; forceps; post-partum flooding.	Recovery and slight pyrexia.	Alive.

* Several, number not known.

extremity may prolapse. Prolapse of the cord would appear to be more common after the use of the bag than in ordinary cases of placenta prævia: it occurred four times in the 40 cases in which the bag was used but only three times out of the 54 other cases. In two cases a vertex was changed into a transverse presentation. The hand in one case prolapsed and of two other cases a breech was changed to a vertex and vice versa. Such a change of position of the fœtus or prolapse of cord or extremity is of little practical moment, since internal version can be performed as soon as the bag is expelled and is usually the easiest and safest method of delivery, especially if flooding recurs after the bag is delivered. The treatment after delivery of the bag was: 16 cases, internal version; seven cases, forceps; two cases, decapitation; two cases, external version; and ten cases, natural delivery.

As to inserting the bag, the question arises whether it should be pushed through the placenta or up alongside the placenta between the latter and the uterus or through a hole in the membranes. In a case of complete placenta prævia it may be impossible to separate the placenta far enough up to reach the membranes, and, again, in the absence of pain, rendering the *ovum tense*, it may be difficult to penetrate the placenta in order to insert the bag through it. It is noted that in three cases the bag was passed through the placenta, in six cases through the membranes, and in eight cases between the placenta and uterus; the results were equally good with each method, hæmorrhage being controlled. It might be thought that inserting the bag without rupturing the membranes or perforating the placenta and thus draining off the waters would raise the intra-uterine tension to such an extent as to risk a rupture of the uterus. This did not occur, nor could I find any such case recorded; moreover, it is very easy whilst filling up the bag to feel the latter as it swells with a hand on the abdomen, and so judge of the tension of the uterus and bag. It has been supposed that the pressure of the bag on the placenta by diminishing the supply of oxygen to the fœtus would increase the fetal mortality. The mortality of this group is about 62 per cent., which is about the same as Charpentier gives for over 2000 cases; it is higher than the general fetal mortality for the whole collection and does not show one of the minor advantages of the bag—namely, a reduction in the fetal mortality, as I will show later to be the case in a larger collection from various writers.

The advantages from the use of the *de Ribes* bag are: 1. Ease of introduction; it is certainly easier to introduce a bag than to perform bipolar version, the only other general method useful in severe cases. 2. Efficient means of treatment can be used at an earlier stage of labour than by any other method; dilatation of the cervix is seldom needed; in only one of these 40 cases was this necessary. A bag can be inserted through an os that admits little more than one finger; while for bipolar version the os should admit two fingers comfortably. 3. Arrest of hæmorrhage is certain; gentle traction on the stalk of the bag will suffice to check any bleeding, or slight weight extension from two to four pounds may be used if the bag has to remain in a long time and pains do not come on. 4. Uterine contraction is stimulated. 5. Little discomfort is caused and there is no risk of sloughing such as may occur from the use of a tampon in the vagina.

Results obtained by various methods of treatment.—I have collected from various authors 249 cases of placenta prævia treated by means of the *de Ribes* bag which show the following results: 249 mothers, 8 died, i.e., 3.2 per cent.; 222 infants, 68 died, i.e., 31 per cent.—the best result of any large number of cases both for mothers and infants. The results of various authors by bipolar version are: 420 mothers, 28 deaths, i.e., 6.7 per cent.; 256 infants, 61 per cent. Separation of the placenta from the lower zone of the uterus has given good results: thus Murphy had a series of 29, of which no mothers died. This method, although physiological, cannot be relied on for general application, since in the absence of pains there is no reason why separating the placenta should stop hæmorrhage; on the contrary, there is a great danger of the hæmorrhage being made worse. Separation of the placenta is generally done whilst performing bipolar version or inserting a bag and in combination with a trustworthy method of controlling hæmorrhage is useful.

Of results obtained by a tampon in the vagina Auvard gives the following figures: 253 cases, 73 mothers and 100 infants died. As many of these date from pre-antiseptic

days it is perhaps hardly fair to compare them with modern results. But supposing half of the deaths to have been from septic complications—a very liberal estimate—the deaths from hæmorrhage would still amount to 15 per cent. Moreover, Auvard, an advocate of the tampon, found that hæmorrhage was not controlled in one-third of the cases; also extreme pain, to say nothing of sloughing, had been brought about by this method.

Of recent years Cæsarean section has been proposed as the treatment of placenta prævia. Tait published a successful case in 1899 and later Conroy and Donoghue have each saved a patient. But in spite of these brilliant results, reckoning no less to the skill of the surgeons than to the stamina of the patients, the mortality with this treatment is very high. Out of ten cases which are reported five died; *accouchement forcé* was not more deadly. Certainly the death-rate for Cæsarean section has been reduced in selected cases to near zero. But a patient who has just had a big flooding will seldom be an inviting subject for Cæsarean section. The matter is well summed up by Palmer, who advocates Cæsarean section only in cases where the os is undilated (I would rather say undilatable) or hæmorrhage is uncontrollable, the child is alive and at term, the temperature of the patient is normal, the patient is not greatly reduced by loss of blood, and the environment is suitable: a combination of events likely to prove extremely rare. There are two obvious fallacies in the arguments of those who advocate Cæsarean section as an "ideal treatment" for placenta prævia. First they imagine the mortality of placenta prævia to be far higher than it is; thus the figures given by Simpson are 29 per cent. Tait magnified this to 40 per cent. and believed that it was really 50 per cent., whereas under suitable treatment it is under 10 per cent. In the second place they think that the first end in view is the rapid emptying of the uterus; this should, however, only be the final objective, the immediate aim being to control hæmorrhage by pressure on the bleeding points.

CONCLUSIONS.

The line of treatment to be pursued in these cases is that which surely arrests hæmorrhage at the earliest possible moment; the only certain means of doing this is by pressure on the bleeding points. The progress and completion of labour, though they may assist in stopping hæmorrhage and ultimately do stop it, are secondary matters. Primary treatment is not directly concerned in hurrying on labour except in the slighter cases, although the methods employed do so incidentally. In a fair number of lateral and marginal, very rarely in central, implantation, the flooding may be quite trifling and no treatment will be needed beyond the slightest. It must, however, always be borne in mind that a placenta implanted on the lower segment, though not causing flooding, may quite suddenly and unexpectedly do so, especially if the placenta becomes partially separated and labour pains cease. Kirg, indeed, found that the apparently slight cases had a greater mortality than those more severe, presumably because in these cases the medical attendants were less on their guard. It is therefore important, even in apparently trivial cases, to watch carefully, or, if from lack of time this should be impossible, to take measures so that flooding cannot occur. Early diagnosis is essential for efficient treatment. A certain number of cases are only seen when the patient is so drained of blood that recovery is wellnigh impossible.

It is necessary, therefore, in cases of ante partum hæmorrhage, in which the os will not admit a finger, to ascertain, by bimanual and abdominal examination whether or not the placenta be implanted on the lower segment, since these cases can almost certainly be saved if treatment be undertaken early. Labour, if not in progress, should be induced immediately, since completion of labour is the ultimate cure. Should the os not admit a bag or performing bipolar version it must be dilated till one of these modes of treatment can be adopted. Such a preliminary *manœuvre* is seldom necessary. In the only case of this nature, No. 2, after dilating to 22 Hegar, the bag could be inserted. Sponge tents have been used with success by Jungbluth and are well spoken of by Barnes and Spiegelberg. Palmer advocates plugging the cervix with gauze for this purpose. Manual dilatation has its advocates. Case 56 shows this method may end in disaster. When the os is of suitable size a bag is inserted or bipolar version is performed, the choice lying with the bag, if one be to be used, since it can be introduced through a smaller cervix and the technique is somewhat easier. Immediate

TABLE GIVING PARTICULARS OF 94 CASES OF PLACENTA PRÆVIA—(Continued).
GROUP D.—Cases not Treated or in which only Minor Treatment was used—(Continued).

No. of case.	Age.	Previous pregnancies.	Months pregnant.	State of labour and of patient.	History.	Treatment.	Result.	
							Mother.	Child.
72	32	4	7	Os uteri one finger.	—	Ergot; membranes ruptured; forceps.	Recovery; normal.	Dead
73	22	0	7	Os uteri less than one finger.	Flooding a few hours.	Ergot; membranes ruptured	Recovery and pyrexia.	Alive
74	29	8	8	Os uteri two fingers.	Flooding 10 days.	Ergot; fetus born in membranes.	Recovery; normal.	Dead
75	29	3	7	Os uteri two fingers.	Flooding 3 days.	Natural delivery.	" "	Alive
77	30	3	—	—	Prolapsed cord.	Placenta, cord and face born together.	" "	Dead
78	44	9	—	—	—	Nil; some post-partum flooding.	" "	Alive

adopted. In two cases the placenta was central. The condition of three cases was grave. The flooding was checked by the treatment. There were two cases of post-partum hæmorrhage—one, an alcoholic, was pulled out of bed by her inebriated friends shortly after delivery; the other was a curious case of recurrent severe metrorrhagia persisting for seven weeks and only cured by hysterectomy, no cause for the bleeding being found. One case died the day after delivery, apparently from septicæmia contracted before treatment was undertaken, so this death can hardly be set down to any failure in the method used.

Group B.—21 cases were treated by internal version or manual delivery in the case of pelvic presentations. Of the 21 mothers five died, and of the 22 children 14 died. This series shows a mortality almost equal to the worst results of 100 years ago; there are several factors to account for this. In five cases the placenta was inserted centrally. Nine of the patients were in a very precarious condition when first seen. In five cases the os was considerably dilated and seen. In five cases the os was flooding for some time. This probably the patients had been flooding for some time. This group, then, contains an exceptional number of severe cases. Four cases died soon after delivery, in from four to 13 hours. Two of them as the result of collapse from the ante-partum hæmorrhage—one of which was a twin labour moribund from the first. The other two succumbed to post-partum hæmorrhage with atony of the uterus. Two cases suffered from septicæmia and one from sapræmia; one of the former died at the end of three weeks—this case had been with some difficulty saved from succumbing to ante-partum hæmorrhage. In this group there were six pelvic presentations, of which three mothers and four infants died; 14 cases of internal version, of which one mother and seven infants died; and one case of version in twins, of which the mother and both infants died. The mortality of version is not so high, then, as appeared at first glance and gives fair results in suitable cases. The cases, however, in which version is indicated are frequently severe, since considerable dilatation of the os must be present to make internal version a fair proceeding,

and the mortality will naturally be higher than that for labour with methods which can be used at an earlier stage.

Group A.—40 cases were treated by the insertion of the de Ribes bag. None of the mothers died. 25 of the infants died. In eight cases the placenta was central. Ten cases were severe. In none of the cases did the os uteri dilate more than three fingers, or, in other words, treatment was used at a comparatively early stage in all these cases. It will be noted that the proportion of central placenta prevails the same in this as in Group C, but the proportion of severe cases is considerably less in the present series. It seems reasonable to suppose that the early adoption of treatment which controlled the hæmorrhage kept down the number of severe cases. The bag once introduced never failed to control the flooding and to induce labour, though the latter was at times a lengthy matter. In the 32 cases in which time is given the bag was expelled as follows: in from 5 minutes to 5 hours, 14 cases; in from 6 to 12 hours, 8 cases; in from 12 to 24 hours, 5 cases; and in from 24 to 36 hours, 5 cases. It has been objected that the prolonged sojourn of this instrument in the uterus makes for sepsis. There is some truth in this: of the 40 cases, 4 had a slight rise of temperature on the third to the fifth day, 7 suffered from slight sepsis or sapræmia, 1 developed bronchitis, pleurisy and parametritis lasting six weeks, and 1 had pneumonia. That is to say, only two cases had any septic trouble beyond the slightest and no case died. It does seem, however, that a slight degree of sepsis or sapræmia was rather more common after the use of the bag than in the other cases. Another objection made is that filling up the bag to separate the placenta more and so increase the hæmorrhage. This cannot occur if the bag be inserted through a hole in the placenta or membranes and does not occur if the bag is pushed between the placenta and uterus, since any bleeding point exposed by stripping the placenta is at once pressed by the expanding bag and the hæmorrhage is thus controlled. The bag may displace the presenting part, and the cord or

attacks nervous and muscular tissues. In the acute stage of diphtheritic toxæmia acute degenerative changes occur in certain cells of the central nervous system and amongst these cells the nucleus of the vagus is affected and extensive fatty degeneration occurs in the muscular fibres of the heart. It is thus that acute diphtheritic poisoning proves fatal, the patient dying from a primary progressive failure of the heart as the result of acute degenerative changes in the neuromuscular mechanism of that organ. At a later stage of the disease, if the patient survives, the poison attacks the peripheral nerves and voluntary muscles; a primary parenchymatous degeneration occurs in the nerve and fatty degeneration in the muscle. The vagus nerve may be attacked along with other nerves and an infiltration of round cells may occur in the intermuscular substance of the heart. The conditions which we have to treat are therefore of a degenerative nature and they are, moreover, *acutely* produced, which renders them considerably more fatal than chronic changes of a similar nature. It must also be remembered that not only is the muscular power of the heart affected but that its regulative mechanism is also interfered with. A fact of the greatest importance in treatment is that the degenerative changes in the heart found in the acute stage of the disease, if a fatal dose of poison has been absorbed, are of themselves capable of bringing about a primary failure of the heart and death, but that the changes found in the later stages of the disease do not lead to death except through the interposition of some strain which the heart is unprepared to meet. The majority of patients, if they survive the acute stage, show some signs of heart failure either in the direction of irregular action or dilatation of that organ. Pathological investigation has further led to the discovery of a specific antitoxin to the diphtheritic poison and thus the treatment of heart failure in diphtheria would seem to be reduced to the simple measure of giving a sufficient dose of antitoxin; but although this is indeed the fundamental principle to be adopted yet it will be seen by a study of the various circumstances in which heart failure occurs that certain auxiliary measures may be adopted, and are indeed necessary, since it is comparatively rare that a sufficient dose of antitoxin has been given before degenerative changes have already occurred in the heart.

I shall first direct your attention to two most important points in the administration of antitoxin. The first point is that it is absolutely necessary to administer antitoxin at the earliest possible moment, since this is a means not of treating heart failure but of preventing the occurrence of changes which lead to it, and that the earlier antitoxin is given the less chance is there of heart failure subsequently supervening. The administration of antitoxin leads directly to the neutralisation of the toxin. If a fatal dose of diphtheria toxin is mixed in the test tube with sufficient antitoxin to neutralise it and the mixture is then injected into an animal no symptoms result. If less than this amount of antitoxin is used the resulting symptoms are proportional to the amount of toxin unneutralised; in such a case no acute symptoms may supervene but the animal may become subsequently paralysed. The same result is seen even if an additional amount of antitoxin is immediately injected. If the toxin is injected intravenously and if after a few minutes the antitoxin is injected the animal will die unless a very large dose of antitoxin is used. If a longer interval is allowed to elapse the animal cannot be saved. The toxin becomes very rapidly combined with the particular tissue affected by it and is then only neutralised with great difficulty by the antitoxin; after it has produced its effects on the tissues it cannot be neutralised. In human diphtheria the toxin is not suddenly poured into the blood as in an experiment but is formed slowly and therefore it is possible to neutralise it by large doses of antitoxin; it should, however, be borne in mind that extensive fatty degeneration of the heart may be found in three days. From experiment we therefore learn that if antitoxin is to be of any service it must be given at the earliest possible moment. Clinical observation also bears out this point. The statistics of the Chicago health department show that of cases first treated by antitoxin on the first day of the disease the mortality is 0.42 per cent., of those first treated on the second day 1.54 per cent., on the third day 3.59 per cent., on the fourth day 11.38 per cent., and later than the fourth day over 23 per cent. Other statistics are in entire agreement with these, only varying a little in the figures. These statistics include cases dying from laryngeal obstruction and also complications, but the vast

majority died from heart failure and therefore the immense importance of the early administration of antitoxin in preventing this is strikingly manifest. In making a prognosis also in a case of diphtheria, one of the first points to be considered is the day on which antitoxin was first administered. I say first administered, because a subsequent dose is undoubtedly useful in some cases in which the membrane has shown no signs of separating or goes on increasing in extent. It should be an invariable rule that immediately diphtheria is suspected in a patient and without waiting for a bacteriological examination, antitoxin should be at once administered as soon as it can be procured. This should be done however slight the case appears to be, because although the severity of the local lesion is, speaking generally, a measure of the severity of the systemic poisoning, an apparently mild case may be followed by marked symptoms. We have no idea of the individual susceptibility of the patient to the disease, neither have we any idea of the number and virulence of the bacilli present.

The second point with regard to the administration of antitoxin to which I wish to refer is that it should be given in large doses. I have already mentioned that if antitoxin is given subsequently to toxin experimentally a much larger dose is needed to prevent acute symptoms and death than if the two are mixed together before injection; and moreover, Ehrlich has demonstrated by partial neutralisation of toxin by antitoxin that the latter is much more efficient in averting death in the acute stage than in preventing the subsequent paralysis. Here again clinical observation is in entire agreement with experiment on these two points and it is found that the mortality is lower when large doses of antitoxin are used and also that to modify the subsequent paralysis large doses are necessary. Fixing the dose of antitoxin is difficult but most authorities agree that 4000 to 6000 units should be the minimum dose for an ordinary case. In the severe cases when larger doses are necessary the question arises whether 4000 units should be given at once and repeated at short intervals until, say, 12,000 or 24,000 units or even more have been injected, or whether the larger dose should be given at once. Personally I cannot see the advantage of small and repeated doses over a massive dose. I think that in a severe case of diphtheria 12,000 to 24,000 units should be given at once and if on the next day there is no improvement in the nasal discharge or separation of the membrane, or if the membrane has extended, the injection should be repeated. In the worst cases some clinicians inject up to 30,000 units at once and repeat the injection in 24 or 48 hours. There is no danger in the antitoxin and the complications that are liable to ensue such as rashes, joint pains, and so forth, are not much more likely to follow large injections than smaller ones. Besides the severity of the case as a guide to the dosage of antitoxin, the time at which it comes under treatment is of importance, a larger dose being necessary on the third or fourth day than is necessary on the first or second day. Time may be also saved if the case is seen late by injecting the antitoxin intravenously. In all other cases subcutaneous injection should be employed, as antitoxin is practically not absorbed at all by the stomach or rectum. The dose is the same for children as for adults.

The point next in importance to the early administration of antitoxin is *rest* both physical and mental. By the term "rest" I mean the avoidance of all causes likely to throw any strain upon the degenerate heart. In the treatment of heart failure due to any cause whatever rest is an important factor because in these circumstances the heart has a diminished amount of work presented to it, but in the treatment of heart failure in diphtheria apart from the administration of antitoxin rest is the important factor and in the majority of cases it is the only one of any use whatever. In the acute stage of the disease when the heart is failing sudden death may occur at any time as the result of the strain of vomiting or jumping up suddenly in bed. If the acute stage is survived and the patient left with signs of heart failure due to changes not in themselves sufficient to kill him strain may again determine sudden death. On the other hand, if he have no signs whatever of heart failure the strain of getting up too early in the progress of the disease often initiates it, thus bringing into evidence the latent heart weakness. Causes leading to heart failure in the later stages of the disease are mental excitement or shock, sudden exertion, vomiting, and respiratory paralysis. The point which I wish to emphasise here is that in the vast majority of cases after the first three weeks of the disease have

treatment is now complete since slight traction on the stalk of the bag or on the leg of the foetus effectively stays further hæmorrhage by causing an inverted cone to press on the lower uterine segment; delivery can now be awaited with equanimity, the strength of the patient being supported as much as is necessary. It matters little whether the bag be pushed through the placenta or membranes or between the uterus and placenta. Ergot was given in several cases with no bad result. In a case with a very rigid cervix ergot might possibly do harm in the first stage of labour by tiring out the uterus in overcoming the resistant cervix and so lead to atony and post-partum hæmorrhage later; for this reason ergot was not given early in Case 2. Moreover, tension on the stalk of the bag is enough to put a stop to flooding. After the bag is delivered, unless the head or breech is driven down by strong pains, internal version is the best course, since flooding occurred in several cases after the bag was expelled. In these cases the insertion of the arm for version acts as a plug till the foetus is turned and can in its turn act as a plug. The alternative of applying the forceps may be rendered difficult by the distance the head is up and by the placenta baulking the operator. Although nothing untoward happened in the seven cases thus dealt with in this collection yet the forceps is of bad repute in the treatment of placenta prævia, for King mentions ten cases with a mortality of 30 per cent. and Auvar 21 cases in which the forceps was used at the "moment of election" with a mortality of 45 per cent.

If the os be considerably dilated when the case is first seen internal version or bringing down a leg in pelvic presentations seems to be the indication; inserting a bag would only increase the amount of manipulation without corresponding advantage. As has been already pointed out, the high mortality of cases suitable for this plan of treatment is due to the fact that so many of them are in a very dangerous condition when first seen. Having met the first indication—namely, checking the hæmorrhage—the next point is to keep up the patient's strength. In severe cases the quickest method is by auto-transfusion, or, in other words, raising the foot of the bed on chairs. Next in rapidity of action is intravenous infusion of saline solution. The latter, though a simple proceeding in a hospital or decent house, where some assistance and clean water can be obtained, may yet in the hovels of the poor prove a very different matter; the water may be so full of extraneous matter as to block completely fine tubes and cannulae. It is here that normal saline solution given per rectum is of the greatest service; it is rapidly absorbed and can be quickly given with a Higginson's syringe. The rectum of freshly delivered women is surprisingly enduring of liquid refreshment. From four to six pints can be given in this way in from one to two hours without any discomfort or return. The weak point about this method is that it cannot be used till labour is complete, whereas intravenous or subcutaneous infusion can be used as soon as hæmorrhage is controlled. With regard to the third stage of labour, it is well to remember the comparative frequency of adherence of a placenta prævia, and consequently there is reason to remove the placenta manually more often than in normal cases.

CASE A.

Recorded for the difficulty in diagnosis; probable rupture of varicose veins of the vagina; gross hæmorrhage; plugging; recovery.—An English multipara with a badly ruptured perineum and slightly contracted pelvis was advised to have labour induced at eight and a half months. There were very large varicose veins of the legs extending on to the vulva and up the vagina. The patient was on an inclinable table and I had just got so far as to begin inserting a bougie for the purpose of inducing labour when the patient strained for two or three times. In a moment there came a gush of hæmorrhage as if a large jug had been upset. Swabbing away blood to look for a bleeding point was out of the question. A clenched fist thrust into the vagina and raising the pelvis also failed. Owing to the ruptured perineum blood poured out all round. The patient was already blanched and nearly pulseless. I hurriedly rolled a sterilised towel into a ball and pushed it up the vagina, the flooding ceased, though how much from the plug and how much from loss of blood is difficult to say. Not having much confidence in the plugging and thinking it possible that passing the bougie might have detached a portion of a low-lying placenta I thought it advisable to make pressure on any bleeding point which there might be from the

upper end of the lower uterine segment down to the vulva. I therefore, having removed the towel quickly, inserted a de Ribes bag, the os being sufficiently patulous. Having filled the bag with water, I then stuffed the vagina with gauze, at the same time pulling down the bag and so exerting firm pressure on the whole lower part of the uterus and vagina. There was no further sign of hæmorrhage. Although the whole episode had not taken more than ten minutes the patient seemed to be on the point of dying from acute anæmia. Five pints of intravenous saline infusion, however, made her rally and in 12 hours she was delivered of bag, plug, and dead child without further bleeding. She made a symptomless recovery. The exact source of bleeding remained undiscovered.

Ramsgate.

SOME POINTS IN THE TREATMENT OF HEART FAILURE IN DIPHTHERIA.

BY CHARLES BOLTON, M.D., B.Sc. LOND.,
M.R.C.P. LOND.,

ASSISTANT PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL AND TO THE NORTH-EASTERN HOSPITAL.

THE successful treatment of heart failure in diphtheria depends upon a knowledge of the various clinical forms of this condition, of the different periods during the disease when it may be expected to occur, and of the chief circumstances influencing its onset. These points are all quite easily grasped when the essential facts in the pathology of the disease are thoroughly understood. I will therefore, in the first place, take the opportunity of reminding you of these facts. In former times the treatment of diphtheria was directed solely against the local lesion but the recent study of the pathology of this disease has shown that its fatal character is dependent not upon the local lesion but upon the systemic intoxication which results from the absorption of certain poisons and that this poisoning cannot be prevented by any means directed against the local lesion. The latter is only of itself directly dangerous to life when it mechanically obstructs the larynx. The diphtheritic poison has a selective action and especially

¹ A paper read before the Windsor and District Medical Society on Dec. 20th, 1905.

is increased by the tendency of mucus to collect in the bronchial tubes and so prevent free entry of air and free expansion of the lung. Pneumonia may also be present as a complication. A strain is thus thrown upon the heart and at the same time it suffers from partial asphyxia owing to deficient oxygenation of the blood. It follows from this that a heart which was not sufficiently degenerated *primarily* to cause death may *secondarily* do so owing to the extra stress put upon it by respiratory paralysis. Unfortunately, very little can be done for this condition, but one point which should not be forgotten is to raise the foot of the bed so that gravity will assist in draining the lungs and at the same time in keeping the mouth free from saliva which collects when the pharyngeal muscles are paralysed and adds an extra danger by flowing into the larynx and causing asphyxial attacks. Vomiting in association with paralysis acts as a strain to the heart, as in the acute stage of the disease, and may lead to death from heart failure. The best treatment for this is to stop all food by the mouth and to feed per rectum or subcutaneously. Drugs are practically useless in this condition. In addition to paralysis coming on during the course of heart failure the latter may first appear just preceding the paralysis, especially when such paralysis has an early onset, or it may first appear during the course of paralysis. When paralysis comes on before the acute stage as ended it is naturally associated with an irregular pulse, as the latter is so common at this stage. When the heart failure first appears during paralysis, occurring at a late stage of the disease, it is the result of a latent weakness of the heart brought into evidence by the paralysis as shown above, or it is due to degeneration of the vagus occurring as a part of extensive nerve degeneration. Whether isolated degeneration of the vagus occurs has not yet been proved.

I come next to the question of the use of cardiac stimulants and tonics. Our knowledge of the exact mode of action of these drugs upon the vascular system is still imperfect, but it is sufficiently definite to guide us in the selection of particular drugs the pharmacological actions of which meet the requirements of different classes of cases of heart failure. At the outset I may remark that the utility of such drugs in treating heart failure in diphtheria is not very great and some of them are contra-indicated. The action of the majority of the heart poisons with which we are familiar is directed not only towards the heart itself but also towards the inhibitory apparatus of that organ and the toxin of diphtheria is no exception to this rule. Not only, as I mentioned above, is there to be found post mortem in patients dead from diphtheria extensive degeneration of the heart muscle, but also degeneration in certain nerve cells in the medulla. This degeneration is especially marked in the motor nucleus of the vagus about the region where Laborde located the vagus centre in the cat by the needle method of excitation. Clinically, we have evidence that the vagus centre is excited in the attacks of slowing with irregularity of the pulse which are so common in the earlier stages of diphtheria. A slow irregular pulse is one of the most fatal signs in the acute toxic stage of this disease. We have seen the dangers of presenting any extra work to the weakened heart and therefore all drugs which raise the blood pressure by excitation of the vaso-motor centre or by a direct action on the arterioles are contra-indicated and all drugs are likewise to be prohibited which act upon the inhibitory apparatus of the heart. This is precisely the action of the group of drugs of which digitalis is a member. In therapeutic doses digitalis slows the heart by stimulation of the inhibitory apparatus and the ventricles more completely empty themselves and contract to a smaller size by a direct action of the drug upon the cardiac muscle. With poisonous doses the inhibitory action may be more prominent, the rhythm of the heart being very slow and irregular and the ventricle dilating more completely in diastole; this inhibitory action may entirely conceal the muscular action. At a later stage, owing to increased irritability, the heart becomes rapid and passes into delirium. The blood pressure is raised by constriction of the arterioles by a direct action of the drug on the muscular walls of those vessels and probably also by its action upon the vaso-motor centre in the medulla. Whether digitalis invariably causes a rise in the blood pressure seems to be a doubtful point, because in the course of some clinical observations upon the blood pressure in cardiac dropsy I have found the height of the pressure to be unaffected by the administration of this drug, although the heart was slowed and the dropsy disappeared. Theoretically,

the employment of the digitalis group of drugs is thus contra-indicated in the early stages of diphtheria when the pulse is slow. Strychnine, which has been employed, is also contra-indicated at this stage because it acts upon the nervous system, slows the heart by vagus inhibition, and raises the blood pressure by vaso-motor constriction. Practically, I have never known a case to be saved by the use of these drugs and I know of no statistics proving that the mortality of the disease is lowered by their employment. This objection does not hold in the case of the cardiac stimulants which are considered to increase reflexly the force and frequency of the pulse and some of which cause vaso dilatation. Alcohol, ether, or camphor are examples of such drugs, but it is extremely doubtful if their employment is of any value whatever in the early stages of diphtheria. It is becoming more and more recognized that the action of alcohol on the heart is in the direction of lessened efficiency. If the patient has received a fatal dose of toxin, antitoxin if given early will save him by preventing cardiac degeneration, but no amount of cardiac stimulation will do any good whatever if antitoxin fails. Cardiac stimulants are therefore chiefly of use in the later stages of the disease when the weakened heart gives way before some strain, leading to a gradual failure or sudden syncope. A paralysed patient at a late stage of the disease who is cold and almost pulseless as the result of vomiting may be benefited by cardiac stimulation, but such a condition in the first fortnight of the disease leads inevitably to a fatal termination in my experience. I have found the application of heat and counter irritation to the precordium to be valuable adjuncts to the cardiac stimulation in the later stage of the disease.

In conclusion, I should like to mention a drug which has not yet received a fair trial in the treatment of heart failure in diphtheria. This drug is belladonna. Of course, it is a very difficult matter to test the efficacy of a drug in such a condition as that the treatment of which we are discussing. It could only be done by testing it upon several hundred patients in various doses, carefully noting the effects upon the circulation and comparing the results with those obtained in a similar number of patients at the same stage of the disease and treated without drugs. The action of small quantities of atropine is to paralyse the terminations of the vagus in the heart and therefore to do away with the inhibitory action of that nerve. The heart is accelerated, the systole increased in extent, the diastolic expansion somewhat diminished, and the output of the heart per minute increased. It could not be expected that the severest cases would be saved by this drug but there are many borderline cases which might be considerably benefited by it, especially those associated with a slow pulse.

Lastly, it should be remembered that the mere presence of irregularity of the pulse or of the physical signs of cardiac dilatation is no indication whatever for the use of cardiac stimulants and that strict rest in bed is the chief requisite for such cases.

Deronsire-street, W.

ON EUCALYPTUS OIL AS A VERNIFUGE IN ANKYLOSTOMIASIS.

By LLEWELLYN POWELL PHILLIPS, M.A., M.D.,
B.C. CANTAB., F.R.C.S. ENG., M.R.C.P. LOND.,

PHYSICIAN TO KASR-EL-AINI HOSPITAL, CAIRO, AND PROFESSOR OF
CLINICAL MEDICINE AT THE EGYPTIAN GOVERNMENT MEDICAL
SCHOOL.

IN the summer of 1905 four male pygmies were admitted into Kasr-el-Aini Hospital under my care for treatment as they were found to be harbouring ankylostomata. They were somewhat anæmic and three of them had enlarged spleen. I proceeded to treat them in the usual way with thymol, though not quite in the full doses on account of their small size and the age of the smallest. The result of the thymol treatment was not good as only two male ankylostomata were expelled from the four. Dr. Looss, the helminthologist to the school, then drew my attention to a method of treatment described by Dr. Hermann of Mons, in Belgium, as employed by him in the treatment of ankylostomiasis in miners, in which eucalyptus oil acted, with the assistance of chloroform, as a vermifuge. I accordingly tried it upon them with the result that the first administration

passed death from heart failure will only occur as the result of some complication or strain and that therefore we have at hand a ready means of obviating this to a large extent.

From the foregoing remarks it would appear that rest is a more powerful therapeutic agent after the acute stage has passed than when it is present, because patients are naturally always kept in bed during this stage of the disease and heart failure leading to death at this time occurs independently of any external circumstances. And it is a fact that the key to the successful treatment of heart failure in diphtheria is antitoxin to prevent death in the acute stage and rest to prevent death in the later stage, after antitoxin has done what it is able to prevent cardiac degeneration. There are, however, borderland cases in which the presence or absence of strain in the acute stage may mean the death or recovery of the patient. Every case, therefore, however mild it may appear, is to be strictly confined to bed during the period of acute symptoms. A careful watch must be kept upon the heart and pulse and since the latter varies from hour to hour when heart failure has commenced it must be frequently examined during the day and if possible during the night, or else if only casually examined at the morning visit it might appear to be quite normal. In fatal cases the first signs of heart failure commence usually about the end of the first week, in some cases earlier than this, and death occurs with great regularity usually within the first 14 days. The signs to be observed are irregularity and weakness of the pulse, together with undue rapidity or slowing. A slow irregular pulse is of bad prognostic significance. The first sound of the heart is short and feeble, the pulmonary second sound accentuated, and the impulse may be diffuse and slapping. When these signs are present the patient should be kept lying with the head low and disturbed as little as possible. Great care should be exercised in syringing or making applications to the throat, as it is a common report from the nurse that the patient became "very collapsed" after syringing; in such a case as this very active treatment should be discontinued or there will be a danger of sudden syncope. Another danger lies in the strain produced by vomiting. Every medical officer who has had charge of diphtheria wards must have been an eye-witness to cases of sudden death resulting from vomiting. The first case I saw die suddenly was that of a little girl in the diphtheria ward of the old University College Hospital. She was suffering from heart failure during the acute stage and showed no symptoms whatever except a gradual failure of the heart that was progressively advancing. On the thirteenth day of the disease she asked for a little jelly which was given her by the ward sister whilst I was standing by; immediately after swallowing the nourishment she raised herself up to vomit and fell back in a faint; after three or four gasps at intervals she was dead. Great care must therefore be exercised in the giving of nourishment and medicines lest vomiting be excited; medicines as a rule are useless and should rarely be given in the acute stage of diphtheria. The early vomiting in diphtheria is usually independent of food and in my opinion the evidence is largely in favour of its being central in origin; it is extremely difficult to control and rectal feeding should be resorted to, drugs apparently having no beneficial effect on it whatever.

Dr. G. O. Garratt, late of the London Fever Hospital, is greatly in favour of washing out the stomach repeatedly. He claims success by this method combined with the administration of belladonna but it has not yet been sufficiently tried for an opinion to be definitely stated as to its value. I should think it would not be always a simple matter and might entail the risk of syncope, as many children would struggle considerably.

The next point which arises in relation to the question of rest is, How long should a case of diphtheria be kept in bed? We have seen that in fatal cases the heart symptoms commence about the end of the first week or even earlier, and that death usually occurs during the first 14 days of the disease and exceptionally a day or two later than this. In the case of patients who do not die directly from the toxæmia the majority show some signs of heart failure, but these commence rather later than in fatal cases. They commonly begin about the end of the second or during the third week of the disease, although in some cases they may appear at the end of the first week. In these cases when heart signs have supervened prolonged rest in bed is necessary. The general rule, which must be always adhered to, should be that, however mild the case appears to be, the patient should

be kept in bed for three weeks from the onset of the disease, and this is all the more necessary since the throat may have been clear of membrane for a day or two before the heart symptoms, which will lead to a fatal issue, appear. If at the end of three weeks no irregularity of the pulse or signs of dilatation of the heart have appeared the patient may be allowed to sit up for an hour or two on a couch during the day and each day the time of sitting up may be lengthened until the patient is at the end of a week able to walk. All this time the pulse and heart must be carefully watched, because often the effort of getting up is sufficient to bring into evidence a latent weakness of the heart which caused no signs so long as the patient was lying in bed. If any signs of heart failure are brought into evidence by the exertion of getting up the patient must immediately be put back to bed again and remain there until the signs have disappeared.

If the patient has survived the first 14 days and is left with an irregular pulse and probably with his cardiac impulse outside the nipple and a systolic apical murmur audible the question arises, How long is it to be expected that these signs will last? Although, of course, it is impossible correctly to answer this question yet we are not altogether without knowledge on this point. The period during which the pulse remains irregular varies within considerable limits; in the mildest cases it may be only ten days or a fortnight and in the most severe four or five months. I have recently seen two patients who were suffering from heart symptoms following diphtheria. One of them, a child, aged four years, had suffered from diphtheria five months previously and the mother complained that if he got excited or ran about he became blue and short of breath; the pulse was 132 in frequency and quite regular; the cardiac impulse was just outside the nipple in the fifth left intercostal space and the first sound was short. The other case was that of a boy, aged 11 years, who had fainted twice within six months. He had suffered from diphtheria four years previously and at the time of examination the pulse was irregular and intermittent, the heart showing no signs of dilatation. This case shows that at very late periods following the disease a latent weakness of the heart may be brought out as the result of strain. The more degeneration there is produced in the heart the longer will the signs last; therefore in all severe cases showing heart failure the patient and his friends must be warned that prolonged rest in bed will be necessary, possibly for more than eight weeks. I say more than eight weeks, because cases have been recorded of sudden death occurring when the patient has been allowed to get up after being kept in bed two months. I have never heard of death occurring suddenly after the third month, therefore, if at this time the signs still persist, the patient may be allowed to sit up and gradually regain his old habits. The general rule would then be that as long as the pulse remains irregular the patient should be strictly confined to bed but that after the third month, although the irregularity may not have quite disappeared, strict confinement to bed is not absolutely necessary. All signs of dilatation of the heart may have long disappeared before the pulse regains its regularity. It is not always an easy thing to persuade the patient that confinement to bed is necessary, because he has absolutely none of the usual symptoms accompanying a heart lesion, such as dyspnoea and so forth, and therefore will not believe that there is any danger. I have known such a patient receive a wholesome warning in the shape of a fainting attack when he attempted to disobey orders. Besides confinement to bed, sitting up and playing with toys must be forbidden in the earlier stages, the bowels must be made to act easily, the diet should be plain and nourishing, and it is all the better for most patients if the friends can be excluded.

Paralysis may come on whilst the pulse is irregular but it does not affect the prognosis or treatment materially unless the respiratory muscles are paralysed or vomiting commences. The normal effect of inspiration on the circulation of the blood is to aspirate blood into the heart from the extra-thoracic veins and thus aid in the diastolic filling of the right heart; at the same time the circulation through the pulmonary capillaries is rendered more free and hence more blood flows to the left side of the heart and the circulation is thus materially aided. If the respiratory muscles are paralysed the movements are slower and more imperfect and thus an obstacle is opposed to the diastolic filling of both right and left sides of the heart; at the same time this effect

last summer. The woman applied for treatment at the Bourne Valley Dispensary. The appearance of the "sore" of which she complained was that of a large mature vaccine vesicle and on inquiry I learned that her baby had been vaccinated a fortnight before and that the arm had "taken" well. The exact manner in which the virus had been transferred could not be ascertained. The baby's finger-nail

seems the most probable instrument of inoculation. The lip, as the illustration shows, was much swollen and it was very painful; there was considerable constitutional disturbance—pyrexia, headache, &c. These symptoms subsided in a few days and the vesicle ran the usual course.
Parkstone.

A FURTHER CONTRIBUTION TO THE STUDY OF MENTAL FATIGUE IN SCHOOL CHILDREN.

BY DR JOSEPH BELLEI,
OF THE BOARD OF HEALTH, BOLOGNA, ITALY.

It is very useful to compare the mental fatigue produced in school children by the afternoon lessons (1) when there is only a short rest between the forenoon and the afternoon lessons and (2) when this rest is greater, in order to see if this last system of school hours is better than the first one. In my treatise on "Mental Fatigue in School Children" I have collected the results that I obtained with regard to afternoon teaching when this began only three-quarters of an hour after the conclusion of the forenoon classes, the interval of rest being from 12 noon to 12.45 P.M. and I am therefore in a position to compare these results with those I obtained last year, in which the afternoon lessons began two hours after the conclusion of the forenoon classes, the interval of rest being from 12 noon to 2 P.M. During this time the poorer children received a meal supplied at the public expense and those who were better off went to their homes.

As in the year 1900 I used the dictation method in these researches and in order to be able to compare the results obtained at two different periods I employed last year at the

beginning and at the end of the afternoon classes the same dictation exercises as in 1900; I also took care that in the new one prepared for the experiments of last year the children should find the same difficulties as in the other two. The schools in which the trials were made were the same in which I experimented five years ago. The first dictation was given to the children at 2 P.M. when school was resumed for the afternoon classes, the second at 2.45 P.M., and the third at 3.30 P.M. during the last half hour of the lesson. For the correction and counting of mistakes I used the same method that I used in my work of 1900, reckoning separately mistakes and corrections made by the children. I also counted the children who did not make mistakes and divided the others into groups corresponding to the number of mistakes that they had made.

I do not report here the results obtained in all the classes but I have summarised them as if there were in all only two containing children of the average age of 11 years and eight months. I also show here the tables exhibiting the results obtained in 1900 in order that I may be able to compare the latter with the former and draw the conclusions that follow from the comparison.

TABLE I.—Boys' Schools: General Summary of Results of the Year 1905.

Trial.	Hours (p.m.)	Average age.	Written letters	Mis- takes.		Differences.	Auto- corrections.		Boys who did not make mis- takes.		Average of mistakes for every boy.	Below the average.	
				Total.	Per cent.		Total.	Per cent.	Total.	Per cent.		Total.	Per cent.
1	2	11 years and 8 months.	97,474	330	0.338	—	63	0.064	157	48.1	1.01	244	74.8
2	2.45		95,368	811	0.841	+0.503	111	0.115	50	15.7	2.55	192	60.5
3	3.30		93,820	1,849	0.859	+0.018	140	0.141	57	17.5	2.62	190	58.6

Boys.—Table I. shows in a concise form the results obtained last year in schools for boys. It will be seen that after three-quarters of an hour of lessons the boys made a percentage of mistakes 0.503 greater than the corresponding number obtained at the moment of the beginning of lessons after the midday rest. Also the percentage of auto-corrections was 0.051 higher at 2.45 P.M. than at 2 P.M. and the percentage of the boys who did not make mistakes fell from 48.1 at 2 P.M. to 15.7 at 2.45 P.M. At 3.30 P.M. the percentage of mistakes augmented only by 0.018 and that of auto-corrections by 0.026, while the percentage of boys who did not make mistakes rose from 15.7 to 17.5. The general results are that from the moment of the beginning of the afternoon lessons at 2 P.M. to the moment of the end of the school at 3.30 P.M. the percentage of mistakes augmented by 0.521 and that of the auto-corrections by 0.077, while the percentage of the boys who did not make mistakes diminished by 30.4 and the average of mistakes for every boy went from 1.01 to 2.62.

TABLE II.—Boys' Schools: General Summary of Results of the Year 1900.

Trial.	Hours (p.m.)	Average age.	Written letters.	Mis- takes.		Differences.	Auto- corrections.		Boys who did not make mis- takes.		Average of mistakes for every boy.	Below the average.	
				Total.	Per cent.		Total.	Per cent.	Total.	Per cent.		Total.	Per cent.
5	12.45	11 years and 4 months	57,600	650	0.730	—	69	0.073	61	20.89	2.19	162	55.4
6	2		53,340	1,348	1.503	+0.773	124	0.133	17	5.86	4.64	174	60.0

From Table II. it will be seen that in the year 1900, during the same period of time—namely, after two hours of lessons—the percentage of mistakes for every boy augmented

¹ Bologna Regia Tipografia, 1901. A short article of mine on the same subject appeared in THE LANCET of May 11th, 1901, p. 1330.

yielded 150 worms and the second 30 more; they unfortunately left for England before a third dose could be given. After this striking result I determined to try the method in other cases and during the summer I employed it at the hospital, not only on my own cases but also on those of my colleague during his absence on leave.

Our previous routine method was as follows. After the patient had fasted during the day a gramme of thymol was given in cachet in the evening; on the next morning the dose was repeated and followed by a purge. But often the drug produced great depression of the heart with slowing of the pulse, and artificial stimulation in the form of strychnine and strong coffee had to be resorted to, and fatal results had even occurred. The patients on thymol were therefore always a source of anxiety to the sister in charge and to the hospital orderlies and much time was wasted in watching them. A safer method was therefore much to be desired.

The treatment below described fulfils, in my opinion, this requirement and has been followed, when properly carried out, by very good results. I do not, however, consider it absolutely perfect, as there are occasional failures, but I am certain that it is more successful than thymol is in such doses as can be given in safety. Dr. Hermann described in his paper several methods of treatment—with thymol, filix mas, and eucalyptus, but concluded that the last drug was the most successful; his formula was as follows: eucalyptus oil, 2 grammes; chloroform, 3 grammes; and castor oil, 40 grammes. This formula I used at first and then, finding that no ill effects were produced in many cases, I increased the doses as follows: eucalyptus oil, 2.50 grammes; chloroform, 3.50 grammes; and castor oil, 40 grammes.

The following is the routine method employed by me now at Kasr-el-Aini Hospital. About 6 P.M. the patient takes a saline purge (though this is not absolutely necessary, as for a long time I discarded it, though, perhaps, it is better not to omit it) and then fasts all night. On the next morning at 7 o'clock he takes half the above mixture and in half an hour's time he takes the other half. He is kept in bed still fasting until the bowels act. Should any depression occur after the first half of the drug the second half is omitted. (This happened in the case of the youngest pygmy who only took half the dose.) In young boys and feeble anæmic patients the dose is divided into thirds and given with twenty-minute intervals. The dose can be repeated every other day. This effects a considerable saving of time necessary for treatment. As a rule, from three to four liquid stools follow, though sometimes only one. Dr. Looss, who examined the stools in the earlier cases for me, tells me that in the first stool there are no worms, and that in the first solid stool after the medicine has ceased acting there are also no worms. He found further that the worms are expelled alive. This may account for the absence of worms in the solid stools as the worms may have time to recover and reflex themselves.

Occasionally the first administration is not successful, though why I do not know, and again very occasionally after one or two negative results a few worms appear. This may be accounted for in some instances, as Dr. Hermann suggests, by the fact that the worms, having entered through the skin just before admission, have not reached the gut until after the lapse of some time. Though in one case (which will be referred to again) a few days after an unsuccessful administration some worms were found *in situ* at the post-mortem examination.

The earlier cases were examined by Dr. Looss, but later I detailed a student week by week during the summer to examine the stools. Unfortunately, however, owing to stress of work on several occasions the stools were thrown away unexamined and so the results are not quite so full as I should like them to have been.

In 44 cases it was wholly successful, as one or more further doses of the eucalyptus mixture yielded no more worms. In some, also, one or more doses of thymol were given with the same object and the same result. In 21 cases a single dose was sufficient, one confirmatory dose of the eucalyptus mixture being given in 15, two extra doses in four, and in one two doses of the mixture and two doses of thymol with negative result. In four of this series thymol had been previously given before the eucalyptus was tried. In 16 cases two administrations were sufficient, as confirmatory doses showed. In some of these, as already mentioned, the first dose was unsuccessful and in several others the second dose expelled more than the first dose. In three cases three doses were necessary and in four cases four doses were given.

One of these latter cases is very instructive. The first dose having expelled no worms thymol was given twice with a negative result; the patient was then given eucalyptus five times—the first three of these expelled worms whilst the last two doses yielded none. In 26 other cases, including the pygmies, it was very efficient, but the patients left hospital before confirmatory doses were given; thus in one case after 76 worms were expelled by the first dose the patient insisted on going home. So whether these were completely cured or not is uncertain.

In the majority of cases, with the exception of a first administration, if a negative result was once obtained further dosage expelled no more worms. The following instances are exceptions: 1. A man, aged 20 years; the second dose expelled none but the third expelled 76 and the fourth 33, the fifth being negative. 2. A man, aged 20 years; the fifth dose expelled none but the sixth expelled six. 3. A man, aged 25 years, who was extremely weak and anæmic, took the eucalyptus mixture on July 22nd, with the result that 47 worms appeared; a further dose on the 26th expelled none; he died on the 29th and 21 worms were found post mortem. (This case is not included with the successful cases above.)

In 29 other cases the mixture was given in some for diagnosis and in some for treatment. In 23 no worms appeared, in five the stools were lost, and in another thymol expelled two worms after two doses of eucalyptus had failed. In three other cases the following results were obtained. In one after the first dose of the eucalyptus mixture the stools were not examined but a dose of thymol expelled 13 worms; a second dose of eucalyptus yielded none. In another the first dose of eucalyptus expelled one worm; then thymol expelled four and a further dose of eucalyptus five. In the third a dose of eucalyptus and a dose of thymol were unsuccessful but a second dose of thymol expelled ten and a dose of eucalyptus seven; a final dose gave a negative result.

The most successful cases were as follows. A first dose expelled 329 worms, a second none. In another the first dose expelled 270 in spite of previous dosage with thymol. In a third the first dose expelled 37, the second 300, and the third none. In a fourth case the result of the first administration was not examined but the second yielded 150 and two further doses none.

That the chloroform is essential is shown by the fact that in three cases where the ova were present chloroform water was given in error instead of chloroform, with a negative result. Thus the treatment has been employed in 103 instances (the cases in which chloroform water was given being excepted), in 44 of which it was entirely successful and in 26 efficient, and in the other 33 the result was either unknown or else negative, the treatment being employed in some for diagnosis, or else mixed treatment was adopted. In one case, that of a patient who died, it was only partially successful.

I think, however, that it is obvious from a consideration of the above results that the treatment is satisfactory with reference to its vermifugal effects. Further, it is not unpleasant for the patient, the long fasting being unnecessary and the taste of the mixture not offensive. It is cheaper and repetition being possible three times a week the stay in hospital is shortened. Lastly, the absence, or rather rareness, of cardiac depression as a result is a good feature. All these facts make it an advance in treatment. As regards the dosage, if the patient be strong and fairly healthy I give the larger dose, but if very young (12 years of age or so) or very weak the smaller dose given in thirds. Oxyurides are freely expelled by it and I have used it in one instance to expel a tapeworm with success.

Calco.

ABERRANT VACCINIA.

By M. EDEN PAUL, M.D. BRUX., M.R.O.S. ENG.,
L.R.O.P. LOND.,

PUBLIC VACCINATOR TO THE PARISHES OF PARKSTONE AND LONGFLEET,
POOLE UNION.

A VACCINATION vesicle in an anomalous situation is perhaps no very great rarity; they are always worthy of report as awkward questions of diagnosis may be raised by them. I was fortunate enough to secure an excellent photograph of a case of this kind that came under my observation

oedematous and closed. On the 22nd the swelling extended to the right side of the nose. On the 23rd pustules appeared on the left cheek, then on the right leg, chest, and left forearm, till they gradually spread over the whole body. An ulcer appeared inside the left nostril discharging greyish-brown pus. There was no albuminuria throughout the illness. The patient was now semi-comatose and became unconscious 24 hours before death. The temperature ran up to 107° just before death which took place at midnight on the 24th. On the 23rd a culture was made from the blood and some fluid was withdrawn from the right knee-joint.

Necropsy.—The face, right arm, and both legs were much swollen, the skin pitting on pressure. There were swellings and pustules as described above. The cheek muscles were infiltrated with pus; the mucous membrane of the mouth was very sloughy; there were no nodules on the hard palate. As regards the middle ear there was no pus in either cavity; the maxillary antrum (left side) contained yellow glairy pus (like that in the right knee-joint) and the mucous membrane was studded with a few small yellow nodules resembling tubercles. On the ala of the left nostril there was an unhealthy-looking ulcer exuding greyish-brown pus but the nasal septum was hyperemic only and showed no nodules and no ulceration. The meninges and the brain were normal. The mucous membrane of the neck, the trachea, and the larynx was studded with minute grey and larger yellow nodules, there being no ulceration, while that of the upper part of the oesophagus was studded with nodules similar to those on the wall of the trachea and larynx. The thorax, the pericardium, and the heart were normal. There were adhesions and fluid at the left base of the pleura. On removing the sternum scattered nodules were seen over the surface of the lungs, grey and yellow in colour and varying in size; they were more numerous over the left lung. Of these disseminated glanders tubercles most were on the surface but some were deeply seated in the lung substance. On section some were tough in consistence, others were broken down in the centre and exuding thin fluid; all were surrounded by areas of inflammation. Except for some enlargement of the liver and spleen nothing of importance was found in the abdominal organs. The cartilages of the right knee-joint were healthy and there was no apparent thickening of the synovial membrane. The joint contained a yellow glairy fluid like that in the maxillary antrum.

Bacteriology.—On Jan. 23rd a needle was put into the right knee-joint and some yellow, glairy, odourless pus was obtained; this pus gave a pure culture of an organism which morphologically and culturally resembled the bacillus mallei (a subculture on potato showed yellowish moist colonies which ultimately turned brown). The pus was therefore sent to the Jenner Institute for intraperitoneal inoculation into a male guinea-pig and it produced orchitis and death in 12 days. The cultures made from the exudate of the tunica vaginalis of the dead guinea-pig were not, however typical, and a second guinea-pig inoculated with these cultures remained quite well except for a small swelling at the seat of inoculation. In explanation of this apparent discrepancy Zieler¹ is quoted by Bulloch² as showing that inconstant results are obtained as regards a typical "Strauss reaction" when pus from a human source is directly inoculated, whereas with pure cultures the result is unequivocal. I made the mistake here, therefore, of using the pus instead of the pure culture for inoculation. The blood culture grew staphylococci only and further cultures made at the post-mortem examination from the pustules and nasal discharge were contaminated with cocci and other organisms.

Histology.—A section through a nodule in the lung showed a mass of leucocytes in the centre, surrounded by epithelioid tissue, in which the alveoli were obliterated; further out the alveolar walls were much thickened and catarrhal cells were present in the alveoli. Sections of lung stained for organisms by Noniewicz's method showed some rod-shaped bacilli which were not, however, Gram negative and were probably putrefactive (the post-mortem examination was made 26 hours after death). The sections were kindly undertaken by Dr. Helen Chambers and further ones of the liver, the kidney, the spleen, the submaxillary gland, the nasal septum, the nasal ulcer, the pustules on the skin, the nodules in the larynx and maxillary antrum, the muscle of the face,

and the bone marrow were stained and searched for micro-organisms with the same disappointing result. I think, however, in some of these a few faintly staining organisms can be made out resembling bacilli mallei.

Remarks.—I should like to point out the close resemblance between this case and the second case reported by Dr. E. W. Goodall in THE LANCET;³ both cases were mistaken for rheumatic fever at the onset and in both the bacillus mallei was isolated from fluid obtained from a knee-joint. Secondly, the still closer parallel between it and the case mentioned in a leading article in THE LANCET,⁴ that of a horse-keeper in the employ of the Andrew Star Omnibus Company. In this case there was an onset with pleurisy, followed by pain in various successive joints, and the patient was regarded as suffering from rheumatic fever. After admission to a hospital pustules developed and the condition was considered to be one of septicæmia. A day before death it was suspected that the case might be one of glanders and cultures confirmed the diagnosis. Other points of interest in the case which I have recorded are: (1) the long interval between the involvement of the joints—too long for rheumatic fever; and (2) the combination of high temperature with a low pulse and respiration rate; this was well marked throughout the illness.

Portman-street, W.

RUPTURE OF THE UTERUS, WITH ILLUS- TRATIVE CASES.

By THOMAS WILSON, M.D. LOND., F.R.C.S. ENG.,

OBSTETRIC OFFICER AT THE GENERAL HOSPITAL, BIRMINGHAM;
HONORARY MEDICAL OFFICER, BIRMINGHAM LYING-IN CHARITY.

SOLUTIONS of continuity, with or without loss of substance, may arise during labour in any portion of the parturient canal. In the order of frequency the parts affected are the perineal body and lower end of the vagina, the cervix and upper part of the vagina, and the body and fundus of the uterus. The injuries vary very much in their extent and importance, the gravest being those that affect the body of the uterus and the upper part of the vagina. The lesion may arise suddenly, as in the case of rupture properly so called, or gradually, as the result of ong-continued pressure of a hard part of the fœtus on some particular portion of the genital canal. In the latter case the maternal tissues may be slowly burst asunder in the further course of parturition or they may be destroyed by a process of sloughing that is only completed some days after labour is ended. Ruptures of the uterus and upper part of the vagina may be complete, involving all the coats, or incomplete. In the latter case the lesion most commonly extends from within outwards, the muscular layers being more or less completely sundered; in rare cases the peritoneal coat only is affected or the tear begins in it and spreads inwards into the muscular layers. Where the injury involves the whole of the coats and a communication is established between the cavity of the peritoneum and that of the genital canal it is said to be perforating, as opposed to non-perforating or incomplete where the abdominal cavity is not opened. Estimates of the frequency of uterine rupture during labour vary very greatly, from 1 in 482 labours (Collins), 1 in 3403 (Jolly), to 1 in 4429 (Ramsbotham). The higher proportions have occurred in the practice of lying-in hospitals where there is a larger number of difficult deliveries. Taking the lower ratio as more nearly representing the actual facts, four or five ruptures probably occur every year in the city of Birmingham; many, especially of the graver cases, are, however, not recognised but are certified as deaths from post-partum hæmorrhage or from collapse or syncope following delivery.

Ruptures of the uterus during labour occur more frequently in multipara than in primipara, in the proportion of more than 8 to 1 (Bandl, 12 per cent. primipara). In a first labour the stronger pelvic attachments of the cervix and vagina and the firmer abdominal pressure tend to prevent the upward movement of the contraction ring, while the uterine tissues appear better able to resist excessive tension. When abnormal

⁴ THE LANCET, June 17th, 1903, p. 1361.

by 0.778, and that of auto-corrections by 0.060, whilst the percentage of children who did not make mistakes diminished by 15.03. The average of mistakes for every boy went from 2.19 to 4.64. Between the results obtained in 1900 and those obtained in 1905 there are differences which required to be analysed. In the year 1900 the percentage of mistakes was 0.257 higher than in 1905, whilst the percentage of the auto-corrections was a little smaller. The percentage of boys who did not make mistakes after two hours of lessons was higher in the year 1905 than in 1900, but was higher in relation to those who did not make mistakes at the beginning of the afternoon lessons than to those who made mistakes at the end of the afternoon lessons. In the year 1905 the difference in the percentage between the results obtained at 2 P.M. and those obtained at 3.30 P.M. was 30.6, whilst after the same period of time in the year 1900 it was only 15.03. The average of mistakes for every boy was higher in the year 1900 than in the year 1905, but it was higher also at the beginning of the afternoon lessons immediately after the midday rest and therefore the difference, although great, is less than appears at first sight. From this it may be concluded that the work done by the boys during the afternoon lessons was in 1905 a little better than in 1900, although also in 1905 after only a quarter of an hour's work a great number of mistakes were found.

TABLE III.—*Girls' Schools: General Summary of Results of the Year 1905.*

Trial.	Hours (P.M.)	Average age.	Written letters.	Mis- takes.		Differences.	Auto- cor- rections.		Girls who did not make mis- takes.		Average of mistakes for every girl.	Below the average	
				Total.	Per cent.		Total.	Per cent.	Total.	Per cent.		Total.	Per cent.
1	2	11 years and 8 months.	55,614	177	0.318	—	36	0.064	78	41.9	0.95	78	41.9
2	2½		54,112	349	0.644	+0.326	46	0.085	46	25.8	1.96	83	46.6
3	3½		58,865	434	0.737	+0.093	73	0.124	41	21.2	2.249	129	66.8

Girls.—Table III., which summarises the results obtained in the girls' schools in 1905, shows that after three-quarters of an hour of lessons—namely, at 2.45 P.M.—the girls made a number of mistakes higher than at 2 P.M., corresponding to a percentage of 0.322. The percentage of the auto-corrections went from 0.064 at 2 P.M. to 0.085 at 2.45 P.M. The percentage of girls who did not make mistakes was 16.1 less at 2.45 P.M. than it was at 2 P.M. At 3.30 P.M. the percentage of mistakes was higher by only 0.093 and that of the auto-corrections by 0.039, whilst that of the girls who did not make mistakes diminished by 4.8. Therefore it results that from 2 P.M. to 3.30 P.M. the percentage of mistakes augmented by 0.419 and that of the auto-corrections by 0.060, whilst that of the girls who did not make mistakes diminished by 20.7. The average of mistakes for every girl went from 0.95 to 2.24.

TABLE IV.—*Girls' Schools: General Summary of Results of the Year 1900.*

Trial.	Hours (P.M.)	Average age.	Written letters.	Mis- takes.		Differences.	Auto- cor- rections.		Girls who did not make mis- takes.		Average of mistakes for every girl.	Below the average	
				Total.	Per cent.		Total.	Per cent.	Total.	Per cent.		Total.	Per cent.
5	12½	11 years and 8 months.	36,300	108	0.297	—	26	0.071	58	50.87	0.94	71	52.50
6	2½		37,453	266	0.710	+0.413	46	0.122	23	18.40	2.12	82	65.60

The results obtained in the year 1900 and set out in Table IV. show that during two hours of lessons the percentage of mistakes augmented by 0.413 and that of the

auto corrections by 0.051, whilst that of the girls who did not make mistakes diminished by 32.47. The average of mistakes for every girl augmented by 1.18. The differences between these two trials are so little that one can conclude that the results obtained from the girls were identical in the year 1905 and in the year 1900.

From the two tables which summarise the results obtained in 1905 it will appear that in respect of quality there is very little difference between the children's school work done at 2.45 P.M. and at 3.30 P.M., but that, on the other hand, there are great differences between the school work done at 2 P.M. and at 2.45 P.M. The fact that the quality of the school work is almost the same at 2.45 P.M. and at 3.30 P.M. proves that after three-quarters of an hour of afternoon lessons (even if there is a two hours' interval between the forenoon and afternoon classes) the children are so tired that their work is full of mistakes and becomes only a little worse after another hour of lessons. As the results obtained in the boys' schools and in the girls' schools were identical, it may be said with certainty—as I have already mentioned in my observations on mental fatigue—that although the children are after the mid-day rest in a condition of mind capable of accomplishing the best work of the day, nevertheless they cannot support three-quarters of an hour of mental application without betraying mental fatigue. Again, the results obtained in the year 1905, when there was a rest of two hours between the morning and the afternoon lessons, are almost identical with those obtained in the year 1900 when this rest was only of three-quarters of an hour's duration. It is therefore obvious that the first method of teaching presents no real advantages over the last one.

The conclusions at which I arrived in the year 1900 are accordingly confirmed by these later researches and I feel myself entitled to repeat with more certainty than ever the following words with which I closed my book upon mental fatigue in school children: "The work done by the children during the afternoon lessons is, on account of the great mental fatigue that it involves, of no advantage to their instruction but is full of danger to their health."

Bologna, Italy.

A CASE OF GLANDERS.

By LOUISA WOODCOCK, M.D., B.S. LOND.,

LATE ASSISTANT PATHOLOGIST, ROYAL FREE HOSPITAL; PATHOLOGIST TO THE NEW HOSPITAL FOR WOMEN; MABEL WEBB RESEARCH SCHOLAR.

A MAN, aged 37 years, a porter in the meat market, was admitted into the Royal Free Hospital on Jan. 6th, 1903, under the care of Mr. James Berry, to whose kindness I am indebted for permission to publish this case. The illness apparently began on Dec. 1st, 1902, with a slight attack of pleurisy, which lasted ten days, after which the patient resumed work. While out walking, however, on Dec. 16th he was seized with severe pain in the left leg and for the next three weeks was treated and sent into hospital as a case of acute rheumatism.

On admission the temperature was 102.4° F., the pulse was 96, and the respirations were 26. There was no swelling or inflammation of the hip or leg, but much pain on movement of the thigh; there was tenderness in the region of the hip-joint and down the back of the leg, especially behind the knee; the leg was easiest in the position of semi-flexion. On Jan. 14th severe pain was felt in the right arm and the elbow-joint became swollen; definite swellings also appeared above and below the joint in the subcutaneous and muscular tissues extending half-way up the arm and a quarter the way down the forearm. The skin there was reddened and pitted deeply on pressure and the condition resembled that of cellulitis. Some crepitations were heard over the lungs. The temperature ranged from 102° to 104° and the patient was obviously very ill. The case was now regarded as one of septicæmia. The left ankle and right knee-joint became successively swollen and painful. On the 19th, five days before death, pustules appeared on the right arm over the swollen areas; these were discrete at first, with hard indurated base, varying in size from that of a pin's head to that of a split pea; later these became confluent, breaking down to form serpiginous ulcers. On the 20th a swelling appeared on the left chest, which fluctuated, and the left eyelids became

Another and more generally accepted view is that the contraction ring is a phenomenon peculiar to labour, that it does not correspond to any definite anatomical structure, but that as the direct result of contraction it is formed at a position several centimetres above that of the real or anatomical internal os. On this theory the portion of the body of the uterus between the contraction ring and the internal os is called the lower uterine segment and it is differentiated from the cervical canal by being lined with a smooth decidua which ceases below in a fairly definite line at the level of the internal os. The discussion of the exact nature of the lower uterine segment has become very complicated and prolix, so that it cannot with advantage be entered upon here, and, moreover, the question is one rather of academical than of practical interest. The level of the contraction ring corresponds in front nearly to the place where the peritoneum becomes closely united with the muscular wall of the uterus and this is a little above the upper limit of the empty bladder. In the course of the first stage of labour as the external os dilates the cervix in front is drawn up and carries with it the bladder above the pubes. At the end of the first stage, therefore, the level at which the contraction ring forms is at a position nearly midway between the pubes and the umbilicus.

When any obstruction to delivery exists the uterus continues to contract strongly, its walls gradually becoming thicker and its cavity smaller, so that the ovum is pressed more and more into the lower distensible portion of the parturient canal. In equal steps with this change in relations the contraction ring constantly rises higher and higher until it may become level with, or even higher than, the umbilicus. At first the pelvic fastenings of the cervix, especially the connective tissue at the bases of the broad ligaments, and the utero-sacral ligaments yield and allow the cervix, together with the vagina, to rise higher and higher into the abdomen. The stretching capacity of these fastenings is finally exhausted as well as the distensibility of the vagina and cervix and then any further contraction of the uterus leads to rupture. The liability to rupture is much greater when the lower uterine segment is unequally distended, as, for example, in pendulous abdomen with anteversion of the uterus; in lateral obliquity of the uterus, as frequently seen in multiparæ; in contracted pelvis, when the vertex undergoes Nægele's obliquity; and in transverse presentations, where the side on which the head lies is always more distended.

SYMPTOMS AND DIAGNOSIS.

The mechanism of production of uterine rupture during labour being understood it is possible to deduce principles of treatment. But it is first necessary to be able to recognise at the bedside that a rupture has occurred and it is of even greater importance to be able to foretell that rupture is threatening, because here, as always, prevention is better than cure.

Threatened rupture.—When labour is protracted a careful watch has to be made for the symptoms of beginning exhaustion of the patient. The first and most easily recognised of these symptoms is found in the pulse and when this does not drop below 100 even in the intervals between the pains immediate delivery is indicated. If the labour be still left to itself the general condition of the patient rapidly deteriorates, as shown by an anxious expression of countenance, restlessness, and groaning even in the intervals between the pains, by a rise of temperature to 101° F. or more, and by a gradual increase in the pulse-rate. An examination of the abdomen then shows that the upper contracted part of the uterus forms a firm well-defined tumour in which fetal parts cannot be made out. Across the front of the uterus the contraction ring is seen or felt as a transverse or oblique depression; when first noticeable this is at a position two or three inches above the pubes, and as the uterus retracts more and more the contraction ring gradually rises towards, or becoming more and more clearly defined. Below the lower segment of the uterus takes up more and more of the fetus and forms a rounded swelling tender to palpation. It is necessary not to confound these signs with those present when the liquor amnii has escaped and the uterus has become closely applied to the neck of the fetus; here the sulcus corresponding to the neck may be mistaken for the contraction ring and the broadening of the uterus over the shoulders for the

retracted uterus; in the intervals between the pains, however, fetal parts can be felt. In threatened rupture the round ligaments become stretched so as to form tense cord-like bands running almost vertically. When the contraction ring runs very obliquely across the abdomen and the round ligament of one side only is very tense and easily felt it may be inferred that the lower segment is becoming unequally and dangerously stretched and that unless speedy delivery is effected rupture is imminent.

Actual rupture.—When the rupture actually takes place the symptoms may occur with startling suddenness or may come on gradually. In a typical case labour is progressing with strong pains when in an instant, at the acme of a painful uterine contraction, an intense local pain is experienced, coupled with the feeling of something having given way; the labour pains cease, while the local pain becomes continuous and severe, the face drawn, the eyes dull, and there are great anxiety and feeling of oppression. Symptoms of collapse rapidly set in, shown first in the pulse, which becomes frequent, small, and soft; pallor, cold extremities, cold sweat, hurried breathing, and attacks of unconsciousness with or without convulsions are rapidly followed by the death of the patient. In most cases the blood escapes from the vagina in quantities varying considerably with the tearing and crushing of the parts; the site of the rupture if it can be reached is found to be notably tender; the presenting part of the fetus recedes and becomes more moveable and if the fetus has escaped into the peritoneal cavity may disappear altogether. When the fetus has escaped into the peritoneal cavity a change in the form of the abdomen is observed: the uterine fundus disappears, the abdomen becomes broader, and the fetal parts can be felt with remarkable clearness through the abdominal walls. When the rupture is lateral the empty and contracted uterus may be felt on one side of the lower abdomen. The fetal heart ceases to be audible and fetal movements cease.

In a very large proportion of cases the symptoms are less acute than those above described. Collapse may only gradually develop, sometimes after many hours, or may be absent when the rupture is incomplete or gradual. The amount of shock varies very much and depends not so much upon the size of the rupture as upon the quantity of blood lost and upon the soiling of the peritoneum. Hemorrhage may be concealed and the blood, instead of escaping through the vagina, may be poured out into the peritoneal cavity or extravasated into the pelvic connective tissue. In the latter situation it may give rise to a large subperitoneal hæmatoma at the side of, or behind, the uterus and may raise the peritoneum and form a mass extending even as high as the kidneys. Much less commonly emphysema occurs; crepitation due to the presence of air may be felt in the uterine wall; or the air may be pressed into the pelvic connective tissue and thence spread to the mons Veneris, the thighs, and over the abdomen as high as the chest. From such a uterine emphysema fatal air embolism may arise.

Sometimes symptoms of bleeding with a moderate degree of local pain are the only phenomena of the first few days even in large ruptures. In some cases, usually when the whole or the greater part of the child remains in the uterus, the labour pains may continue. In a few recorded instances of rupture following version, internal or external, the patient has died in a few days after delivery without having shown any of the usual symptoms of rupture.

In the upper part of the vagina perforating ruptures occur similar in their importance to uterine ruptures. In this position lacerations appear to be relatively more often due to external violence; the vagina may be torn from the cervix in front, behind, or even all round. The imminence of rupture in this situation cannot be so easily detected as in the case of the lower uterine segment, although extraordinary tension of the vaginal vault may sometimes be observed as a warning sign. When rupture takes place here bleeding is usually less profuse than in rupture of the lower uterine segment; labour pains do not so suddenly cease and shock is, as a rule, less because the child's body only gradually escapes into the peritoneal cavity. Prolapse of the intestine is more frequent in these cases and may lead directly or indirectly to a fatal issue as in Case 1 about to be related. The prognosis is grave: out of 47 cases collected by Ludwig 27 died—six from hæmorrhage, 16 from peritonitis, and five from other complications. The treatment depends upon the same principles as that of rupture of the uterus itself.

In the following case a rupture had occurred in the posterior vaginal fornix probably as the result of criminal

stretching of the lower uterine segment has once taken place it is probable that in subsequent deliveries over-stretching occurs more readily and quickly. Moreover, in multiparae the uterus is often to be found displaced to one side, or in the case of a pendulous abdomen to the front, so that excessive stretching easily takes place at one part of the circumference of the lower uterine segment. Rupture is relatively more frequent in poor people than among the well-to-do and in elderly women because of the influence of repeated deliveries. The child is more frequently male; Spiegelberg found 48 boys in 67 cases, a proportion of more than 2 to 1. Predisposing causes, congenital or acquired, may be present in the uterus. Among the congenital conditions, anomalies of development of many kinds, as, for instance, incurviform, arcuate, one-horned, or double uterus, may be accompanied by abnormal thinness of the walls, especially at the fundus in the neighbourhood of the tubal angles, and in rare cases the thinning may be so great that, just as in tubal gestation, rupture takes place either spontaneously or after an injury. Frequently also in malformations there is congenital narrowing of the cervical canal and of the external os, so as to give rise to obstruction in delivery.

A predisposition to rupture is sometimes acquired, as where Caesarean section has previously been performed, or where lacerations followed by cicatrization have occurred in previous labours. In recent years certain methods of performing vaginal fixation have given rise to rupture in succeeding labours. Sometimes the growth of a tumour is a cause, as in certain fibroids and in cervical cancer; in a collection of 180 cases of labour complicated by cancer Herman found that no less than 11 of the patients died from rupture of the uterus. Abnormal friability of the tissues has been described in many cases and may be caused by certain local chronic degenerations and indurations the result of chronic metritis; in many cases of placenta prævia this friability is well marked. The intimate nature of the changes is not understood; fatty degeneration has been suggested but not proved; a similar condition of easy lacerability without obvious lesion is occasionally observed about the perineum and is as little understood there as in connexion with the uterus and vagina. In one of the cases about to be related (Case 2) this friability was extremely well marked. Rupture scarcely ever occurs except when labour has been of long duration and the liquid amni has long drained away. It may happen, however, while the external os is still narrow, especially when the presenting part is high and no proper bag of membranes has been formed. Very rarely the accident has occurred while the membranes were intact; in such cases the membranes have been said to be very resisting, and the lower segment has been weak and thin walled.

In the great majority of cases the accident depends upon mechanical difficulties in the passage of the child, of which the most common are contracted pelvis, transverse presentation, and hydrocephalus. In 230 cases collected by Merz contracted pelvis was the cause in 70, transverse presentation in 26, and hydrocephalus in 18 cases. In cases of extreme pelvic contraction obstetric interference takes place as a rule earlier and rupture is less common than in those of moderate degree. In the latter cases the head is early driven into the brim and may there fix the lower end of the cervix, while the lower segment of the uterus becomes expanded upwards and thinned. Incarceration of the end of the cervix is, however, not essential and is not a common factor in the causation of rupture. Exostoses and hard tumours in the pelvis may bore through the peritoneum and lead to rupture from without inwards. Hardness and rigidity of the external os and cervix, consequent on the presence of tumours or on cicatrization of former lacerations or sloughings, may cause rupture of the lower uterine segment. Excessive size or hardness of the head of the foetus or of its body, as in a case from which a specimen has been placed in the Birmingham University Museum, or faulty position as in face or transverse presentations may lead to the accident. Presentation of the placenta is also a common cause of rupture because of the alteration in structure and elasticity of the lower uterine walls consequent upon the development of the placenta in an abnormal situation.

Ruptures are commonly distinguished according to their apparent causation into spontaneous and traumatic. The former are due to deficient power of resistance of some part of the uterine or vaginal wall relative to the pressure brought to bear upon it. Traumatic ruptures require to be divided

into those in which the violence directly produces the lesion and those in which the external force merely hastens an accident already impending. They may be due to the hand or to instruments. Among the latter may be mentioned the forceps, cephalotribe, sharp and blunt hooks, and last, but by no means least, Bossi's dilator and its numerous modifications. The introduction of the hand in performing version may cause laceration, especially if it is not kept quiet and spread out during the pains; or rupture may happen while the foot is being found and brought down, or especially while the foetus is being actually turned. In such cases the accident is shown by the occurrence of bleeding and by the operation suddenly becoming exceedingly easy. As a general rule, even where the lesion appears to be due to injury by the hand or instruments, the way has been well prepared by the previous course of labour, and the trauma is merely the last straw. Even here, however, a higher degree of skill might in many instances prevent the occurrence of rupture. The rupture usually begins in the cervix and lower uterine segment, whence it may be prolonged upwards into the body of the uterus and downwards into the vaginal vault. The next most common position for the rupture to begin is in the upper part of the vagina and the least common situation is in the uterine body. The direction of the tear is generally oblique but may be transverse particularly when it is seated low down, or longitudinal especially when it occurs laterally; in the last case the rupture is often merely a prolongation of the tear that naturally occurs in the cervix during labour. The borders of the rupture are usually ragged, torn, thinned, and infiltrated with blood; in many cases the walls of the uterine body are found to be enormously thickened.

It has already been stated that in the great majority of cases rupture of the uterus depends upon mechanical obstruction to the completion of labour. The manner in which the accident is brought about was first satisfactorily explained by Bandl in papers published in 1875 and since then his mechanical theory has formed a firm groundwork for our knowledge. To understand Bandl's theory it is necessary first of all to consider the changes that naturally take place in the parturient canal in the process of labour. At the end of pregnancy the body of the uterus forms a large bag evenly and completely filled by the ovum. The cervix is by comparison little changed; its walls are soft and its cavity, often slightly dilated, is filled with thick jelly-like mucus. In multiparae the cervical canal measures from three to four centimetres in length, but in primiparae already before labour begins the upper half or more of the canal becomes dilated and taken up into the general uterine cavity, so that there is apparent shortening to two centimetres or even less. The walls of the uterus vary very much in thickness but on a rough average it may be said that those of the cervix measure one centimetre and those of the body rather more than half a centimetre. In the course of labour the parturient canal becomes differentiated into two portions with opposite physiological functions. The uterine body with the exception of its lower segment actively contracts to expel the ovum, while the lower segment, together with the cervix and the vagina, forms a passive distensible cylinder, a kind of delivery tube or excretory duct. The walls of the uterus become thicker and the cavity smaller as the ovum is forced downwards; the vagina, cervix, and lower uterine segment, on the contrary, become gradually distended into a thin-walled cylinder with a diameter of four inches or thereabouts. The length of this cylinder may also measure four inches even in normal circumstances. In this condition the position of the internal os is no longer recognisable to the touch, although on anatomical preparations the decidua can be seen ending abruptly at the junction of body and cervix. The distinction between the active and passive portions of the canal becomes marked sooner or later after the beginning of labour and when the hand is introduced for any purpose into the uterus the limit between the two portions may be recognised as a more or less prominent ridge; in obstructed labour the distinction becomes much more marked and is often visible and palpable through the abdominal wall as a groove or depression running transversely at some distance above the pubes. This boundary marked as a prominence on the inside and a depression on the outside of the uterus, is called the contraction ring. Much discussion has taken place upon its nature and exact relations. According to some observers it corresponds to the internal os, on which view the whole uterine body contracts and only the cervical canal takes part in the formation of the thinned and expanded portion of the parturient canal.

TREATMENT.

It is of the utmost importance to have clear ideas of the best treatment to pursue in a grave emergency such as is rupture of the uterus occurring during labour. Hesitation and delay may be as fatal as the employment of wrong methods. The treatment falls naturally into two divisions—preventive and curative. Prevention consists in the correct management of cases of obstructed labour, especially in the second stage, and includes a proper appreciation of the methods of effecting delivery in these cases and of the indications for putting them into practice. Two golden rules must never be forgotten. The first is that when there is any reason to suspect a cause for obstruction to labour ergot must never in any circumstances be administered until the child is delivered. The second is that in a case of obstructed labour, where the waters have escaped and the signs of tonic contraction of the uterus are present, version must not be performed. In exceptional cases some authorities consider it good practice to make a careful trial of version under deep anaesthesia when the child is still alive, because this is a sign that the stretching of the thinned lower uterine segment is not yet extreme; but as a general rule even when the child is living perforation of the head or decapitation is to be preferred, because the interests of the mother are paramount and her life is in imminent danger.

In protracted labours with strong pains a careful watch should be kept upon the condition of the uterus and of the round ligaments. The position of the contraction ring should particularly be observed, especially during a strong pain, when it may sometimes be seen. In the slighter degrees of pelvic contraction the ring is not always sharply marked, since the presence of the head may lend firmness to the lower segment; careful examination during and between the pains will, however, enable us to distinguish the hard contracted uterine body from the softer distended lower segment and cervix. Of even greater importance is the condition of the round ligaments; when on the threatened side the ligament seems to be inserted at an unusually high level of the fundus and when marked tension persists even in the intervals between the pains there is always a considerable degree of stretching of the lower uterine segment.

When the signs of threatened rupture become marked immediate delivery must be effected. If the external os is not fully dilated multiple incisions or the hydrostatic bag may be employed. The method of extraction of the child must not increase the stretching of the already over-distended lower segment; as a rule, therefore, in vertex presentations perforation is to be preferred to the use of the forceps and in transverse presentations decapitation must be performed.

When rupture has actually occurred the treatment falls into two divisions: first, the extraction of the child and of the placenta and membranes; and secondly, the management after delivery. The delivery of the child may have to be undertaken either through the vagina or by abdominal section. Wherever possible the first method, that through the vagina, is to be preferred. If the head presents delivery by forceps or version should not be undertaken, but perforation and craniotomy should be performed. If the child has partly escaped into the peritoneal cavity without its long axis being displaced it should still be extracted through the vagina either by craniotomy when the head is presenting or by seizing a foot where this can easily be reached. If the child has mostly or entirely escaped into the peritoneal cavity coliotomy must be undertaken for its extraction and the opportunity seized thoroughly to cleanse the cavity and to treat the ruptured uterus by suture or removal.

When the child has been delivered the rupture still remains to be treated and as to the best method great diversity of opinion still exists. Olshausen teaches that in rupture the most rational treatment is to open the abdomen and suture the laceration but admits that the results are not brilliant. Winckel formerly taught that laparotomy was the best treatment but now is of opinion that drainage of the rupture by gauze through the vagina together with a tight abdominal pad and bandage so as to fix the uterus low in the pelvis is best and that donches should be avoided. Lately the routine employment of abdominal or vaginal hysterectomy has been practised; reference has already been made to Varnier's results by the abdominal method; the vaginal operation has been advocated more especially by Schröder and Winter.

As a matter of fact, no one method is applicable to all cases, but in each case the rupture must be treated on its merits. The main factor in deciding the method of treatment is the probability or otherwise of septic infection being already present. When the patient is probably not already infected and the other conditions are favourable the laceration should be treated on ordinary surgical principles with a view to its union; when, as is usual, there is the probability that infection has taken place the uterus should be removed either by the abdominal or vaginal method and free drainage of the peritoneal cavity should be provided for.

In one of my cases where septic infection had probably not occurred delivery of the fetus by decapitation, hæmostasis by sutures and forceps, gauze drainage through the vagina, and a tight abdominal binder were the means of securing a favourable result. This case afforded a good illustration of the fact that sometimes labour may, so to speak, be latent—that is to say, it may progress for many days without being recognised as such by the patient even when she is an experienced multipara.

CASE 2.—The patient, a large fat woman, aged 41 years, was sent to the Birmingham General Hospital at a little before noon on April 12th, 1898, with a note from her medical attendant saying that he had been called to the patient in labour about 10 A.M., that the child's head was then presenting, and that on passing his hand into the vagina with a view to perform version he found a rent at the upper part of the vagina through which his fingers passed into the peritoneal cavity; he immediately desisted and sent the patient to the hospital. The following history was obtained a few days later from the patient and her husband, both of whom agreed that she had completed about seven and a half months of pregnancy. The first five labours were all straightforward; the sixth child was born with the arm round the neck. In the fifth month of the present pregnancy the woman had a fall on to the left knee. On the last day of March, a fortnight before admission, she accidentally struck her abdomen against a wooden drawer, which caused severe pain, illness, and pallor. Since then she had been unable to go to work because "the waters kept flowing"; presumably the accident caused rupture of the membranes. For the last four or five days there had been pains in the back, something like labour pains, according to the patient's account, but not high enough. There had been discharge like matter for the last two days but no bleeding at any time.

On admission the patient showed only moderate symptoms of shock and did not complain of much pain; the fetus lay with the head to the right and limbs to the front; no foetal heart could be heard. Before examining through the vagina the patient was anaesthetised and the vulva and vagina were prepared in the usual manner before operation; a ragged transverse tear fully four inches in length was found in the posterior fornix just below the cervical insertion. The right hand of the fetus passed through the tear into the peritoneal cavity; the margin of the cervix was found round the shoulder of the fetus; a little bleeding was going on. Decapitation was performed by Ramsbotham's hook and the body of the child was removed by traction; the foetal head was easily extracted by bimanual manipulation with a finger in the mouth. Slight bleeding continued and therefore the placenta was removed five minutes after the birth of the child. The uterus did not contract; injections of hot water were therefore employed, followed by plugging with iodoform gauze and afterwards by the injection of ergot deep into the muscles of the buttock. The rent in the vagina was then closely examined; it was found to extend further on the left side where it was continued into the connective tissue at the base of the broad ligament; the left side of the cervix was also found to be torn deeply. There were numerous freely bleeding points as well as general oozing of blood from the torn surfaces. Some bleeding points were secured by over-casting sutures and three large spurring vessels were tied. Great difficulty was experienced in suturing and tying the tissues which were as friable as wet blotting paper; for this reason no attempt was made to bring any part of the edges of the tear together by sutures. Several pressure forceps were applied to bleeding points and left on. A gauze drain was passed into Douglas's pouch which was clean and clear from blood clot. The vagina was then packed with gauze and a large pad of cotton wool was firmly bandaged over the lower abdomen so as to make pressure through the pelvic brim.

At the end of the proceedings the radial pulse could scarcely be felt. Ten minims of strychnine solution were

abortion. Through the tear a coil of sigmoid flexure escaped into the vagina and as the result of strangulation and infection became gangrenous and escaped as a large slough on the ninth day after the placenta was removed. The operation of intestinal anastomosis was undertaken two months later and resulted in the death of the patient, an unfortunate termination which was due, at least in part, to bleeding from the torn uterus.

CASE 1.—A multipara, aged 35 years, was admitted urgently to the General Hospital, Birmingham, on Dec. 18th, 1902, with the history that she had been losing for three weeks and that a fetus of four months' development had come away on the 16th. A medical man was first called in on the 17th and attempted to remove the placenta under chloroform, but finding a rupture of the vagina he introduced a drain of iodoform gauze and advised the immediate removal of the patient to hospital. The patient was very fat and there was a suspicion that the abortion had been criminally procured. On admission she was anaesthetised and the parts were cleaned in the usual manner. An extremely foetid placenta was removed from the vagina and then a coil of large intestine with shining surface, defiled with blood but not much congested, was found in the upper part of the vagina. The coil was well washed with boric lotion and returned into the peritoneal cavity through a tear which extended for four inches across the posterior fornix of the vagina close to the cervical attachment and outwards behind the lower end of the left broad ligament. The uterus could not be pulled down with volsellæ; it was enlarged and its cavity measured five inches. Douglas's pouch was well mopped out and drained by a large strip of gauze with the lower end left in the vagina. On Dec. 23rd thick faecal material was found on the vaginal packing and an enema returned through the vagina. On the 27th a slough comprising about five inches of large intestine came away. Afterwards the whole of the faeces escaped through the vagina, although the general condition of the patient remained quite satisfactory. Two attempts by the vaginal route were made without success to close the artificial anus, which was situated very high up at the apex of a long and narrow vagina.

On Feb. 28th, 1903, a plastic operation was undertaken through the abdomen with the patient in the Trendelenburg position. A corpus luteum cyst enlarged the right ovary to the size of an orange and this ovary and the tube were removed to give room. Two lengths of large intestine ran down the front of the sacrum to the bottom of Douglas's pouch where they were firmly fixed by dense adhesions to the back of the uterus and broad ligaments and to the front of the sacrum. These portions of intestine represented a long coil of the sigmoid flexure from which the extremity had sloughed off. At the lower end of the right one was an opening admitting the tip of the index finger; the left one was doubled upon itself and no opening could be found into its side or tip until boric lotion was injected through the anus, when the coil distended and the lotion was seen to escape from a hole at the apex not larger than a No. 3 catheter. After separating the intestine from its adhesions the two ends were anastomosed by suture. In holding up the uterus with a volsella to enable the adhesions to the sacrum to be dealt with the substance of the organ was torn widely and there was moderate hæmorrhage from this tear as well as from the adhesions. Catgut sutures were applied to stop the hæmorrhage from the uterine tears, a gauze drain was passed from the bottom of Douglas's pouch into the vagina, and the abdominal wound was closed in the usual way. At the end of the operation, which had lasted one hour and 40 minutes, there was great shock from which the patient never rallied. Death took place ten hours later. At the necropsy all the organs were found to be fatty. In Douglas's pouch were several ounces of black clotted blood which appeared to have come from the torn uterine wall. The anastomosis of the gut was perfect.

The prognosis of rupture of the uterus, always very grave, has somewhat improved since the introduction of antiseptics into midwifery. The result depends on immediate and correct treatment being undertaken. In deciding upon the treatment the child may be left out of consideration, its chance being all but hopeless because of the previous long duration of labour and because after the tear there are hæmorrhage and detachment of the placenta, and sometimes also because the umbilical cord is caught and compressed by the rupture. In 237 cases collected by Jolly only 7.5 per

cent. of the children were born alive, and to arrive even at this figure all cases of craniotomy were excluded. As regards the maternal mortality Hugenberger in 298 cases found only about 5 per cent. of recoveries, while in Jolly's statistics one mother in six, or about 17 per cent., recovered. Recovery is most frequent when the fetus has remained wholly or in part in the uterus, or has been extracted through the vagina. In cases of incomplete rupture the outlook, according to Spiegelberg, is as grave as in the perforating form. Secondary hæmorrhage may be fatal, as in the case in the university museum already mentioned. As a rule death is due to diffuse septic peritonitis or later to suppuration of a hæmatoma, or to purulent peritonitis. Schultz, in a collection of 193 cases of rupture from different authors, reckons that in cases left untreated the rate of recovery is 20.2 per cent.; in cases treated by drainage 36 per cent.; and by coliotomy 44.70 per cent. of the mothers are cured. Statistics of lying-in hospitals give the best evidence of the severity of the accident because the whole of the results are known, favourable and unfavourable. In 80 cases in the Berlin Clinic Koblanck found 56 perforating cases with 47 deaths, and 24 incomplete with 12 deaths. Franz has reported 12 cases occurring in the Halle Maternity; of these, two were incomplete and both died; ten were complete, and of these one was moribund on admission and the other nine were subjected to abdominal section, with only two recoveries. Varnier published 23 personal observations in 1901. 11 were treated from 1885 to 1897 by delivery by the vaginal route followed by plugging; of these only one patient recovered. Between 1897 and 1901 12 cases were treated, of which six were treated by abdominal section and repair of the rupture with three recoveries; in the other six death occurred too speedily to admit of laparotomy. A rupture that has healed may again rupture in the next pregnancy, but several observations are on record in which the patient has safely borne a child one and a half to two years later.

The causes of death are manifold. Shock and hæmorrhage, especially when combined, may be rapidly fatal. If the patient survives the immediate accident and if the fetus is expelled into the abdomen the dangers are the same as those of extra-uterine gestation. Secondary hæmorrhage from an artery in the uterine wall may occur even weeks after the rupture. The bladder may be ruptured and extravasation of urine take place into the connective tissue, or, as above related, a coil of intestine may be caught in the laceration and become strangulated.

By far the most common issue in a patient who survives the primary shock is death from the consequence of septic infection. The risk of infection varies directly with the duration of labour, with the number of vaginal examinations, and with the severity and duration of the manipulations necessary for delivery. Putrescible material is present in abundance and the mucus that ordinarily protects the parts from the evil effects of germs is conspicuous by its absence. The fetus may die in the course of the prolonged labour and may then become putrid; as also may any parts of the placenta and membranes that have become separated from their attachments. Any blood that is present in the canal and all those tissues that have been compressed, torn, or bruised, and have thus been lowered in vitality, also afford favourable opportunities for the growth of germs. The toxins that result are absorbed by the freshly made tears, by the peritoneum in perforating lesions, or at the placental site. The last-mentioned avenue of infection is of extreme importance, not only because infection here is extremely likely to take place but also because of the great difficulty of treating it effectually when complicated by rupture. Even when the laceration of the vagina or lower uterine segment is properly treated and when peritonitis does not arise from this source it is quite possible for the infection of the uterine cavity to cause death from septicaemia or peritonitis. This possibility should, therefore, always be borne in mind and for this reason, as well as because the removal of the uterus affords better drainage of the peritoneal cavity in an infected case, the uterus should be removed when doubt exists as to the presence of infection.

The antiseptic conduct of labour appears in rupture to be useful, not only in preventing the later deaths from infection just referred to but also in diminishing the number of deaths that take place in a few hours from so-called shock and collapse. Rapid absorption of toxins by the peritoneum is probably in these conditions a very important factor in bringing about the fatal issue.

A CASE OF DERMOID TUMOUR OF THE MEDIASTINUM IN A CHILD AGED TWO YEARS.¹

By GEORGE CARPENTER, M.D. LOND.,
PHYSICIAN TO THE NORTH-EASTERN HOSPITAL FOR CHILDREN.

A CHILD, aged two years, was admitted into the North-Eastern Hospital for Children under my care on June 22nd, 1905. In the previous November she had had pneumonia. She was healthy until the preceding July, when she became languid, contracted a cough, and subsequently developed the attack of pneumonia. At this time her chest was noticed to be bulging. Two days before she was taken to the hospital it was noticed that she could not lie down, her respirations were accelerated, and she complained of pain in her side. When admitted into the hospital she was cyanosed; there was sucking in of the lower intercostal spaces, mostly on the left side. The respiration-rate was 60 to the minute, the pulse-rate was 136 to the minute, and the temperature was 99° F. Her ribs were beaded and the anterior fontanelle was patent. The right side of the chest in front was dull from apex to base; over the apex the breathing was tubular in character and elsewhere there was deficient entry of air, passing on to absent breath sounds at the extreme base. On the left side in front there were dullness and tubular breathing above and below the clavicle. On the right side behind the chest was absolutely dull; the breath sounds were bronchial above the spine of the scapula and elsewhere vesicular and diminished but nowhere absent, not even at the extreme base. Over the left apex there were dullness and tubular breathing. The heart sounds were best heard over the fifth rib some little distance outside the nipple line, and accompanying the first sound was a systolic bruit. The liver was displaced; its free edge was felt four fingers' breadth below the costal margin in the nipple line and there was a distinct depression between the liver and the costal margin.

Such were the physical signs gleaned at a hasty examination and aspiration was proceeded with at once in sequence to an exploratory puncture; 13½ ounces of pale straw-coloured opalescent fluid were withdrawn. After aspiration the chest became resonant behind. Air entered quite well all over, accompanied by fine rales. In front the chest remained absolutely dull with deficient entry of air. The patient was again explored just outside the right nipple and the syringe became charged with blood. There was some hæmoptysis, a few drops after the exploration, perhaps half a drachm of blood. The heart sounds were now heard loudest just outside the nipple and the organ had probably shifted half an inch or so towards the mid-line; the bruit had disappeared. The liver receded about a finger's breadth. On closer examination it was noticed that the front of the chest was much bulged; it was rounded in outline and occupied more of the right side than the left. An x ray examination was made and it was reported by Mr. Sale-Barker that the whole of the right lung was opaque to the rays. The breath sounds on the left side became vesicular. After the aspiration the child rapidly improved. When she left the hospital on July 3rd the chest was still dull in front on the right side and the cardiac impulse was in the fifth interspace.

On July 31st the child was brought to the out-patient department cyanosed and moribund. She was re-admitted into hospital and died shortly afterwards. At this time on a hurried examination it was found that the right chest was completely dull back and front and the free edge of the liver was four fingers' breadth below the costal margin in the nipple line. A post-mortem examination was made the same day. The left pleura was healthy as was also the right pleura. In front of the right lung was a mass of the size of a fist. On incising this from six to eight ounces of clear fluid escaped; inside the cyst was some cheesy material with a few hairs lying at the bottom. The rest of the tumour felt hard. The right lung was much compressed. Dr. Theodore Fisher, who examined the specimen, made the following report: "The tumour is roughly spherical. In addition to displacing the heart slightly to the left it projected into the

anterior mediastinum and reached to the inner surface of the left lung. The right lung was compressed into an airless strip which lay behind; the compressed lung did not occupy more than one-half of the space of the lung on the opposite side. On section the tumour is chiefly composed of a considerable number of cysts, the largest of which is the cyst which has been opened. Between the cysts running from above downwards is a partition composed of fat and fibrous tissue and containing a few calcareous masses. Most of the cysts contained a gelatinous material of a light brownish colour. In the large cyst which had been previously opened were sebaceous-looking material and short hairs."

Wellbeck-street, W.

ON THE UNIFORM LINEAL GROWTH OF THE HUMAN FŒTUS.

By R. CADWALADR ROBERTS, B.Sc. LOND.

It is well known that the human fœtus grows in length between the third month and full term at a nearly uniform rate, more especially from the fourth or fifth month onwards, and it is easy to find a rule for estimating the length—in inches or centimetres—of the fœtus for this interval. Thus, we have only to multiply the lunar month of gestation by five and we find the length in centimetres at the particular month.

Age.	Length.
5 months	25 centimetres.
6 "	30 "
7 "	35 "
8 "	40 "
9 "	45 "
10 "	50 "

This rule was given by Haase.¹ Also working in inches we find the corresponding length by multiplying the number of lunar months by two. This result is nearly exact, but if we work in calendar months the result will be about an inch short. Thus:—

Calendar month.	Same x 2.	Length.
5	10	8 inches.*
6	12	12 "
7	14	15 "
8	16	16½-17 "
9	18	21 "

* Galabin: Manual of Midwifery, p. 55.

Hence we have the general rule that the length of the fœtus is a "lineal function of the time" nearly—that is, its length is directly proportional to its age.

Now I may ask, "Does the fœtus grow at a uniform rate in the other two dimensions of space?" I shall try to answer this in two different ways, both indirectly.

1. The fœtus from the third month onwards does not change its shape *very much* as it increases in volume. This change of shape is caused by two factors—viz., (a) the slower rate of growth of the head and (b) the faster rate of growth of the limbs relative to the trunk, for in the earlier months the head is relatively bigger and the limbs smaller than in the later months. We shall see later that these two inequalities compensate one another, so that we can find a very simple rule for deducing the volume (or at any rate a value proportional to the volume) of the fœtus at any particular month. So the approximate adherence to its original shape points to the conclusion that the fœtus increases in breadth and depth at a uniform rate with the length and therefore with time.

2. The specific gravity of the fœtus from the third month onwards does not change much. I know of no experiments made to prove this but I do not think that it does vary much. When the denser parts of the fœtus are forming, such as centres of ossification and great growth of cartilage in the later months, this is also the time when most fat is put on, and this, of course, tends to compensate and keep the density of the fœtus constant. Hence the "mass," or what is usually called the "weight," of the fœtus is directly proportional to the volume of the fœtus at any period.

Now we have the weight of the fœtus at the end of every month given us in text-books. I take the figures below from

¹ The specimen was exhibited at the meeting of the Society for the Study of Disease in Children on Oct. 12th, 1905.

injected during the operation and after the woman was returned to bed a pint of saline solution was injected subcutaneously. The child was a female, 16½ inches long, and weighed three pounds; the placenta weighed 12 ounces. The external measurements of the pelvis were decidedly greater than the average, being 12, 12½, and 9½ inches respectively. 48 hours after the operation the forceps were removed, together with the gauze packing from the vagina and uterus but not from the peritoneum. In passing a small piece of gauze with very little pressure into the vagina the mucous membrane of the vulva was torn on the right side so that there was free bleeding, to control which two silk sutures were required. The abdominal binder was taken off on the sixth day after operation. The temperature remained normal until the evening of the fourth day, after which it rose every evening until the fourteenth day after operation; the highest point reached was 102° 2' F.; on the fourteenth night a stool was passed which was said to contain about two ounces of pus, and thereafter the temperature remained normal until the patient was sent home well on the twenty-seventh day after delivery. In another case, in some respects like this one, similar treatment was not successful, the patient dying from septic peritonitis on the eighth day after delivery.

CASE 3.—The patient, a primipara, aged 25 years, who had a moderately flattened pelvis, sustained a perforating rupture of the vagina in the course of a protracted labour with shoulder presentation. After long-continued efforts at version under anaesthesia the bipolar method succeeded very easily; when the trunk was delivered great difficulty was experienced with the arms and it was then discovered that rupture had occurred. On my arrival the head and arms were still in the uterus; when extraction of the child was completed the rupture was observed to be a large transverse ragged tear in the posterior vaginal fornix close to the cervical insertion; no bleeding was going on and the peritoneal cavity did not appear to have been fouled; a large iodoform gauze drain was passed into the lower part of the peritoneal cavity and the vagina was loosely plugged with the same material. On the following day the patient was removed to hospital; the packing was twice renewed at intervals of two days under chloroform anaesthesia; the patient died from septic peritonitis on the eighth day after delivery. A post-mortem examination was refused.

Sometimes rupture takes place when the cervix is still only slightly dilated and the foetus is still in the uterus. In such cases delivery is best effected by splitting up the anterior wall of the uterus so as to get complete access to the foetus. After delivery the uterus can be immediately extirpated through the vagina. This treatment was successfully employed in the following case where an incomplete rupture occurred during forcible dilatation of the cervix in a multipara whose tissues were friable owing to the development of a placenta prævia. Recovery followed upon the operation, which is now known as vaginal Cæsarean section.

CASE 4.—The patient, aged 38 years, had arrived at about the fifth month of her twelfth pregnancy, all the others having ended normally at term. While out driving very profuse hæmorrhage occurred. On returning home the patient sent for her usual attendant who found the cervix partially dilated and proceeded under chloroform to dilate still further with a view to empty the uterus; when two fingers were in the cervix the patient gave a sudden lurch and the hand was immediately withdrawn. On examining again after the administration of more chloroform a large rent was found in the posterior fornix of the vagina and I was immediately summoned. When I arrived I found there had been a moderate loss of blood; the patient was pale and restless; the firm, enlarged uterus was on the right of the middle line and extended as high as the umbilicus. The cervix was dilated and rigid, admitting two fingers; behind it a large irregular cavity which would have held the fist was filled with blood clot; the hæmorrhage had ceased. Having obtained the necessary assistance I proceeded after incising the vagina and pushing up the bladder to split the cervix and anterior wall of the uterus until a macerated male foetus of about the fifth month could be seized by the legs and extracted. The median incision was then continued as far as the fundus and the uterus gradually delivered. The organ was then completely divided into two and each half was removed after its corresponding broad ligament had been secured by three forceps. The peritoneal cavity was drained with a strip of iodoform gauze.

At the close of the operation the pulse was 90; the extremities were somewhat cold; reaction speedily ensued and the patient made an excellent recovery. Rupture had taken place through the posterior vaginal insertion and extended up into the lower half of the right broad ligament; the vaginal insertion on this side was intact, as was also the uppermost portion of the broad ligament. The placenta had been attached to the right side of the uterus and its border came down to the edge of the internal os; its uterine surface was covered with adherent black blood clot over nearly its whole extent. The wall of the cervix on the right side was exceedingly friable.

The danger of infection of the uterus, the difficulty of treating it should it arise, and the distinct risk of fresh rupture occurring in a subsequent pregnancy should decide us in a doubtful case not to hesitate to sacrifice the uterus in order to save the woman. When the uterus has already been emptied and there is certainty, or distinct probability, that infection has already occurred, the uterus should be removed and this may sometimes be done with success even when septic peritonitis has already begun as in the case now to be related.

CASE 5.—In this patient there had apparently been a transverse presentation due partly to placenta prævia and partly to the presence of a submucous fibroid. The second stage of labour had lasted for at least four days until the contraction ring was exceedingly well marked. When first seen, 24 hours after delivery, the patient was in an extremely grave condition, as septic peritonitis had fairly begun and a sloughing fibroid was present in the uterus. In my opinion it is undoubted that the performance of vaginal hysterectomy was the only chance of saving life. The patient, who was a septipara, aged 37 years, and whose last child was born three years before, was first seen 24 hours after the delivery of a dead seven months child. She was pale and anxious; the pulse was 130; the temperature was normal; there were frequent severe colicky abdominal pains and repeated vomiting and retching. The abdomen was markedly distended and tender; there was visible peristalsis of the intestines; and the hard, round, tender uterus was fixed in the lower abdomen extending half-way to the umbilicus. There was very foul vaginal discharge; the cervix was patulous; in the posterior wall of the cervical canal about an inch above the external os was a small ragged depression and in the posterior wall of the uterus near the fundus was a hard rounded lump which seemed to be nearly as large as the closed fist. On the fifth day before I first saw the patient labour pains were said to have begun; a large bag of membranes protruded into the vagina and was ruptured. On the next day there were two considerable losses of blood; two days later ergot was administered and a few hours later the patient was placed under chloroform, a portion of placenta which was present was removed, and then a foot was seized and the foetus was extracted, the remainder of the placenta and membranes being afterwards delivered by the hand inserted into the uterus. No vomiting occurred before delivery and there were no labour pains for the three days prior to the administration of the ergot. Two hours after I first saw the patient she was anaesthetised and a sloughing submucous fibroid was enucleated by the fingers. The ragged depression in the posterior wall of the cervix admitted two fingers into the peritoneal cavity; higher up at a distance of about three inches above the external os was a transverse prominent ridge—the contraction ring. It was decided to perform vaginal hysterectomy and this was done by splitting the uterus in the middle line anteriorly and delivering the organ; the broad ligaments were each secured by three forceps which were left on. After the removal of the uterus a considerable quantity of black blood clot which had a rather strong odour was swabbed out of the hollow of the promontory. A large drain of iodoform gauze was introduced into the peritoneal cavity. At the end of the operation the patient was collapsed and very pale and the pulse was 160. Within half an hour reaction set in and the patient afterwards made a most satisfactory recovery.

Birmingham.

HOSPITAL SUNDAY AT BRISTOL.—Jan 28th was observed in Bristol as Hospital Sunday. During the past eight years the sum of £12,748 has been raised by this fund and last year £2053 were realised.

neck were stripped downwards for about two inches from the edge of the incision. The flap was then pulled upwards and it was found possible to suture it to the periosteum of the lower jaw. Then the edges of the incision were sutured together just as they were before the cut was made, but the line of incision was now situated just above the lower edge of the jaw instead of being at the level of the hyoid. The wound was dressed with collodion and cyanide gauze and the sutures were removed on the sixth day when it was completely healed. Fig. 2 shows the condition a fortnight after the operation.

Remarks by Mr. W. H. BROWN.—So far as I know, this simple method of restoring the lower lip after complete removal has not yet been described. It may be said: Why make an incision only to re-close it? The answer to this is that the dissection needful to free the flaps causes much bleeding and it would be impossible to ligature with accuracy vessels so far away from the edge of the wound, and much oozing after a plastic operation nearly always means failure.

ELDER COTTAGE HOSPITAL, GOVAN.

A CASE OF HERNIA OF THE VERMIFORM APPENDIX, PROBABLY INFANTILE, AND AFFECTED BY SUPPURATIVE APPENDICITIS WHILE IN THE SCROTUM.

(Under the care of Mr. J. A. C. MACWEN.)

THE patient, a man, aged 25 years, was admitted into the Elder Cottage Hospital, Govan, in May, 1905, complaining of a swelling in the right scrotum which he first noticed a few days previously, his attention having been directed to the part by a sensation of something slowly giving way when lifting a heavy weight. On examination a firm rounded swelling of about the size of a walnut was found situated just above the testicle and connected with it. This swelling was opaque to transmitted light and was not markedly tender to pressure. The vas could not be satisfactorily isolated, as a thick cord ran up from the mass just described into the abdomen through the inguinal canal. There was no impulse on coughing. A large and rather prominent scar over the inguinal region and upper portion of the scrotum attracted attention and the patient explained that this was the scar left by an operation for rupture which he underwent when an infant. As the condition was causing the patient trouble and unfitting him for work operation was decided on.

Operation.—An incision as for the radical cure of hernia was made and the parts were exposed. The mass which had been felt on examination was found to consist of matted omentum, and when this was opened out the vermiform appendix was found within it. The appendix extended from the internal ring to the testicle; it was curled on itself toward the tip and was firmly adherent at this part to the upper portion of the testicle. This adhesion to the testicle was dense and avascular, necessitating cutting to effect a separation, and obviously was of long standing. The appendix having been freed from its adhesions to the testicle was next freed from some slight adhesions to the inguinal canal, and then on applying gentle traction and using the finger as a hook the lower end of the cæcum came into view. Appendectomy was then performed and the stump was umbilicated by a circular suture, after which the bowel was returned within the abdomen. Having removed the protruding portion of matted omentum the operation was completed by performing the final stage of the radical cure for hernia (Macwen's operation)—a mattress suture was passed through the conjoined tendon and its free ends were passed through Poupart's ligament, so that by tightening and tying the ends together the conjoined tendon was pulled down behind Poupart's ligament and thus obliterated the canal. The patient made an uninterrupted recovery, the wound healing aseptically under a single strip of gauze painted over with collodion and was allowed up six weeks after operation. He resumed work about a couple of months later and is now (January, 1906, seven months later) regularly at work without any recurrence of the hernia.

Remarks by Mr. MACWEN.—Judging from what was found at the operation it would appear that the appendix in this case had long occupied the inguinal canal and had as the result of some inflammatory process. The absence of any definable hernial sac also would be accounted for by an old inflammatory process. The recent sensation of something slowly giving way and the subsequent swelling I

attribute to the slipping down into the scrotum of a small portion of omentum.

Being interested in the condition found and having ascertained the ward in the Western Infirmary, Glasgow, in which the patient had been treated when an infant some 23 years previously, I turned up the old journals of that institution and found that he had been operated on for hernia when 20 months old. According to the history there given the patient had a swelling in the groin from the time he was ten months old. A truss was then worn until the week of admission to hospital, when it was discarded as the swelling became large and painful and descended into the scrotum. The swelling increased in size until on admission it was found to be pear-shaped, extending above to the inguinal canal, while the lower portion in the scrotum was hot, red, and painful. There was impulse on coughing but taxis was not successful. The scrotum was laid open when pus flowed out from the tunica vaginalis, after which the bowel was returned "with a slip and gurgle" and the pillars were brought together by a silver stitch which was removed later. Free drainage was provided and frequent lavage was performed.

From the description given in these old notes it appears probable that the patient had a hernia of the appendix from a very early age (which conclusion, as already mentioned, is strengthened by the condition found when operating recently). When 20 months old, however, a suppurative appendicitis occurred, with abscess formation in the scrotum. This abscess was opened by the incision into the tunica vaginalis; the bowel was returned to the abdomen, while the appendix, left to drain through the open wound, gradually healed up, and contracted the adhesion to the testicle mentioned in the description of the recent operation. This same suppurative process, occurring 23 years previously, would account for the absence of any definite hernial sac.

Medical Societies.

CLINICAL SOCIETY OF LONDON.

Exhibition of Cases.

A MEETING of this society was held on Jan. 26th, Mr. H. H. CLUTTON, the President, being in the chair.

Dr. H. D. ROLLESTON exhibited a case of Multiple Lipomata (Adeno-lipomatosis). The patient was a man, aged 43 years, and he had noticed the fatty tumours in the neck for about four years. The tumours were present on the neck, upper arms, and trunk, being for the most part symmetrically situated; there were none on the legs or forearms. Pain did not precede their appearance, as was the case in adiposis dolorosa. No enlarged glands were found and there were no scars from tuberculous glands. There was no loss of muscular power and the knee-jerks were normal. He had had painful swellings of the joints which did not yield to salicylates or to colchicum and he had had several attacks of peliosis rheumatica.—The PRESIDENT remarked on the importance from a surgical point of view of the question whether these fatty tumours were encapsulated or diffuse.—Mr. W. G. SPENCER discussed the pathology and, drawing attention to the local vascularity and the concurrent local fat formation which occurred in these tumours, asked which was the primary or causal agent of these two conditions.—Dr. ROLLESTON referred to the resemblance of this disease in men to adiposis dolorosa in women. The tumours were encapsulated at the outset and afterwards diffuse. The pathology was obscure, but the tendency to hemorrhage suggested vascular degeneration; both this and the resulting adiposis might be the result of alcohol.

Mr. J. R. LUNN exhibited a case of General Paralysis of the Insane (I) in a boy, aged 16 years. The patient was one of eight children and the mother stated that he was always untrustworthy with money and prone to steal. He had had three fits of unconsciousness in 1905, since which time he had become duller in intellect and had had occasional twitchings of the left arm and leg. When walking the left arm was flexed and he dragged his left leg, and there was some weakness of the muscles elevating the mouth. The speech was affected but there were no tremors. The left pupil was larger than the right. There was no history of syphilis.

Galabin. So if we can show that the weight—and consequently the volume—of the fœtus is directly proportional to the cube of the length it must increase in all three directions of space at a nearly uniform rate. But as the length of the fœtus is proportional to the month of gestation, the volume will be proportional to the cube of the age of the fœtus, hence the weight will be proportional to the cube of the age. We shall now see if this latter is so: that is, we shall compare the weight with the "cube of the age." Call the months from the third onwards m . We shall see that m^3 is proportional to the weight of the fœtus at all times from the third month onwards, provided the density is constant and the fœtus increases at a uniform rate in all directions.

Month of gestation or m .	Value of m^3 .	Value of $m^3/104$	Weight of fœtus
3	27	0.26	3 ounces.
4	64	0.61	7½ "
5	125	1.20	1 pound.
6	216	2.1	2 to 2.5 pounds.
7	343	3.3	3 " 4 "
8	512	4.9	4½ " 5 "
9	729	7.0	7 "

So we see that the cube of the age of the fœtus is very nearly proportional to the weight and that the latter can be deduced by taking the cube of the corresponding month and dividing it by a figure—104—which gives the answer in pounds, correct to within one ounce at the third month, and absolutely correct at full term.

This rule holds good from the third month onwards, that is during the period that the placenta is fully formed. It does not hold previously to the third month. So although there are certain irregularities in the rate of growth in the three dimensions and also some variation in the density at different times, yet these to a large extent cut each other out and we are left with a very simple rule for finding the weight at any particular month.

HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed et Causa Morb.*, lib. iv., Proœmium.

GENERAL INFIRMARY, LEEDS.

A CASE OF "COUNTRYMAN'S CANCER," DESCRIBING A NOVEL METHOD OF RESTORATION OF THE LOWER LIP.

(Under the care of Mr. W. H. BROWN, M.Sc. Lond., F.R.C.S. Irel.).

FOR the notes of the case we are indebted to Mr. Harold Leach, house surgeon.

The patient, a man, aged 68 years, was admitted for a large growth situated on the lower lip, involving the whole of the red margin and extending downwards about one and a quarter inches. The edges of the growth were hard and infiltrated. There was no doubt that the condition was epitheliomatous, despite the fact that though the history was a long one no glands could be felt either under the symphysis or behind the angle of the jaw (*vide* Fig. 1). As history it was stated that the growth started seven years ago as a small ulcer on the red border of the lip. The patient had never consulted a medical man before admission.

Operation.—An incision was made round the growth well clear of the edge and the mass was removed, including the whole of the red border and the tissue of the lower lip as far as the margin of the jaw. The growth was found not to have involved the periosteum. A transverse incision about six inches long was made through the tissues

of the neck just above the level of the hyoid bone and this flap was freed. This flap was drawn up into the gap formed by the removal of the growth to form another lip and was sutured at either angle of the mouth; then the tissues of the

A fortnight after operation, the patient having allowed his beard to grow

origin in a female child, aged 13 months. The left brachial and radial arteries were dilated and tortuous and the palm of the hand was occupied by a pulsating vascular tumour. The third part of the left subclavian artery had been ligatured in February, 1905, but without success. 2. A case of Cavernous Nævus of the Tongue, also of congenital origin, in a girl, aged 11 years. In July, 1904, the right lingual artery and veins were ligatured and the tumour apparently completely dissected out, but the present condition showed a gradually increasing recurrence.

Dr. BEEVOR exhibited a case of Perforating Ulcers of the Feet and joint lesions associated with only slight sensory changes, probably due to syringomyelia. The patient was a man, aged 38 years. The symptoms referred to had commenced about three years before. Three pieces of dead bone had separated on various occasions, one of which was the distal end of the terminal phalanx of the big toe. The question of the case being very early locomotor ataxy was considered, but the knee-jerks were increased and there were no other symptoms of that disease. Extraordinary symptoms might be met with in syringomyelia.

ABERDEEN UNIVERSITY MEDICAL SOCIETY.—A meeting of this society was held on Jan. 13th, Professor J. T. Cash being in the chair.—Sir Patrick Manson delivered an address on Some Recent Researches in Tropical Pathology. Regarding yellow fever, he said that Dr Reed of the United States Commission had shown that the bacillus icteroides of Sanarelli had no causal relation to the disease. Dr. Reed was, however, struck by the fact that while the incubation period of the fever was three days that of the epidemic was 15 days. Following up this clue and finding that fomites were ineffectual in transmitting the disease he fixed on the mosquito, *Stegomyia fasciata*, as the culprit. Mosquitoes fed on a patient during the first three days of the fever transmitted the disease after a lapse of 12 days; those fed on the fourth, fifth, or subsequent days did not transmit it. His discovery had led to the stamping out of yellow fever in Havana. Yellow fever might easily become an Asiatic disease once the Panama Canal was completed if the United States Government did not take steps to prevent its spreading. The result of Dr. Reed's discovery had been of inestimable benefit to mankind and to commerce. Sir Patrick Manson then referred to *ankylostoma duodenale*, an entozoon which caused a severe anemia that was very common in many countries. It did not reach the intestine by means of drinking water, as had been supposed. By experimenting on dogs, which suffered from a similar *ankylostoma*, and by observation of the papulo-pustular skin eruption of Assam coolies (commonly called "coolie itch"), it had been shown that the parasite entered by the skin. The ova were passed in the faeces and getting into suitable soil were thus conveyed to the skin, whence the blood carried them to the lungs. Thence they climbed into the trachea and being swallowed reached the oesophagus and the intestine. Isolated cases occurred in this country among people who had lived abroad. He referred to such a case which had been given up as a hopeless case of pernicious anemia but examination of the blood revealed a marked eosinophilia (40 per cent.)—an invariable indication of the presence of an animal parasite. In a Cornish mine which was deep enough to reproduce the tropical conditions of heat and moisture there had been an outbreak of anemia due to this parasite. The recognition of the disease was the chief thing; its treatment was very simple and effective, a few doses of thymol and eucalyptus oil serving to get rid of at least the bulk of the parasites. Sir Patrick Manson then spoke upon trypanosomal diseases. He said that Dr. Dutton had seen a trypanosoma in the blood of a white man in West Africa who was suffering from an obscure fever and he subsequently found it in the blood of natives. In African sleeping sickness the blood also contained a trypanosoma; there was a period during which the brain and spinal cord were unaffected; when they were involved the distinctive lesion was a meningo-encephalitis characterised by a dense perivascular infiltration by leucocytes. How this arose was still unknown. Bruce, in studying nagana of cattle, had found that a species of the tsetse fly transmitted the disease. Search among the tsetse flies of the districts affected by sleeping sickness had led to the discovery that the fly which infected human beings was the glossina palpalis. "Leishman bodies," which resembled a curled-up trypanosoma without a flagellum, were first discovered in the blood of the rat and

then in the spleen of a man the subject of a peculiar fever. In many cases originally put down to malaria they occurred in the spleen, liver, and bone marrow so profusely as even to exceed in weight the weight of the viscera involved. Oriental sore was a localised skin lesion associated with the occurrence of Leishman bodies, but it healed in a few months, and it was a peculiar fact that the subjects of oriental sore were immune from the visceral disease. Regarding the guinea-worm, he said that it had been recently shown that the cyclops, its intermediate host, gained access to the system by drinking-water and was killed by the gastric juice, which at the same time stimulated the contained guinea-worms to activity. Sir Patrick Manson also referred to the spirochæte of relapsing fever and to the oval bodies like coccidia discovered by Dr. John Catto of Aberdeen and now considered to be the ova of a new species of bilharzia.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

—A meeting of this society was held on Jan. 19th, Dr. J. Porter Parkinson being in the chair.—Mr. Arthur Edmunds showed a case of Cutaneous Pigmentation in which there was on the buttocks and back a curious bluish mottling similar to the pigmentation which occurs in a large number of Asiatic races of mixed descent. The pigmentation resembled that shown in a Japanese baby recently exhibited at the society by Dr. G. A. Sutherland. Some held that this pigmentation was an evidence of a negroid ancestor, while others, especially the Japanese, held that it was merely a racial characteristic. In the present instance there was no history of any negroid ancestry.—Dr. George Carpenter showed a case of Sclerema Neonatorum occurring in a girl aged eight weeks. The infant was born in a state of asphyxia but recovered with artificial respiration. There was a brawny induration of a purplish purple hue over the whole of the back and the back of the neck, also over the buttocks and upper part of the thighs posteriorly; also there were two small patches over the occipital region of the scalp.—Dr. Parkinson showed microscopical specimens from a case of Sclerema Neonatorum taken from an eight months' infant who died when ten days old. The sections of the skin showed chiefly thinning of the epidermis with considerable thickening of the cutis vera apparently due to increase of fibrous tissue, but this seemed insufficient to account for the sclerema which he suggested was due to a chemical rather than to a structural change.—Dr. Leonard G. Guthrie showed a case of Lipomatosis. The case was that of a child who was very fat although neither the weight nor the height was abnormal. The discrepancy between the weight and the appearance was probably due to lightness of the skeleton.—Dr. O. O. Hawthorne showed (1) two children suffering from Mental Defect and Optic Nerve Atrophy and (2) a boy aged seven years who had almost completely recovered from an Infantile Hemiplegia which followed a convulsive seizure at two years of age.—Dr. Carpenter and Mr. J. P. Lockhart Mummery showed a case of Hemihypertrophy in a child aged two and a half years, the left side being larger than the right. The face and tongue on the affected side were appreciably larger and the head was half an inch broader. The left side of the trunk was one inch larger than the right, the left arm was half an inch longer, and the left leg was one inch longer and correspondingly enlarged. The bones on the hypertrophied side were also larger.—Dr. Carpenter and Dr. Theodore Fisher communicated notes of a case of Fatal Dilatation of the Heart occurring in a boy aged eight years. The necropsy showed that there was no adhesion of the pericardium, neither was there any valvular disease. Apparently the boy had suffered from symptoms indicating cardiac failure for about a year, but the only history of rheumatism related to an attack four months before admission to hospital. After death the heart was found to be not only dilated but hypertrophied. It weighed ten and a half ounces. Microscopically there was considerable fatty degeneration of the cardiac muscle but this probably was a comparatively recent pathological change.—Mr. Edmunds showed a case in which a Congenital Tumour of the Sacrum had been successfully removed.—Dr. J. G. Emanuel showed an infant with Congenital Absence of the Epidermis of the Hands, Legs, and Feet. In addition, over the temples, the bridge of the nose, and the middle of the lumbar region there were irregular-shaped areas in which a similar congenital deficiency in the formation of the epidermis existed. The parts affected were smooth, free from hair, sharply defined

¹ THE LANCET, Dec. 2nd, 1935, p. 1621.

complete enucleation of such tumours and cited some cases so treated from the literature. The proceeding was certainly attended with considerably more risk, and incision and drainage appeared the safer method though it involved tedious convalescence.—Mr. Mole thought that it was running unnecessary risk to endeavour to excise these cysts from the liver, incision and drainage usually being followed by a satisfactory result.—Dr. J. R. Charles read a paper on Fright in its Relation to Disease. After having described the physiological effects of fright, the analogies between fright and cold as exciting factors in disease were mentioned. Stress was laid on the importance of the avoidance of fright in certain conditions, specially during childhood. Its connexion with such diseases as chorea, hysteria, paralysis agitans, the paroxysmal neuroses, Graves's disease, and the infective and other diseases was discussed. Numerous illustrative cases were quoted.—Dr. J. A. Nixon, Dr. J. O. Symes, Dr. W. S. V. Stock, Dr. Williams, Dr. Shingleton Smith, and Dr. Harrison related cases bearing on the paper.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Jan. 16th, Mr. William Handcock, the President, being in the chair.—Dr. H. J. Campbell showed a case of Hereditary Ataxy of the Cerebellar Type. The patient was a man, aged 41 years, in whom the symptoms had developed during the last six months. The eye symptoms were not well marked. There was general ataxy and the knee-jerks were increased. There was no history of heredity, but on the whole Dr. Campbell thought that the case fitted in better with hereditary cerebellar ataxy than with any other disease.—Mr. J. B. Hall read a paper on some Renal Cases Illustrating the Value of the Urinary Segregator as a Means of Diagnosis. He said that the want of some means whereby the excretion from each kidney could be separately collected and examined was recognised many years ago and such a want was for a considerable time a great hindrance to the development of renal surgery. Even so recently as the year 1904 a surgeon of repute told Mr. Hall that he had a few days before excised the wrong kidney with a fatal result. A correct estimate of the condition of both organs was therefore of enormous importance in renal operations. Cystoscopy and catheterisation of the ureters were hardly available for general use, as they required very highly specialised skill. During the past three years, however, an instrument known as the urinary segregator had been perfected and its use had been attended with the greatest success. The fundamental idea of the two types of this instrument at present in use was the same—namely, the formation of two separate channels along the floor of the bladder through which the urine from each ureter could flow and be separately collected by means of a double catheter. This partitioning of the bladder floor into two separate channels was effected in one of two ways. In the American instrument known as Harris's segregator a lever was introduced into the rectum or vagina and by its pressure on the bladder floor a median ridge was raised along the trigone which effectually divided the bladder into a right and a left compartment, through which the urine ran from the respective ureters. In the French type of instrument the principle was different. The instrument was curved in such a way as to fit snugly along the floor of the bladder when it had been introduced. By turning a screw in the handle an indiarubber curtain was made to rise up and bridge across the concavity of the curve of the instrument, thus forming a partition which divided the bladder into two separate halves. Before using the instrument the bladder must be washed out in order to obtain specimens of urine uncontaminated with any mixed sample present in the bladder at the time of examination. In many cases, however, such information as was required might be obtained without this preliminary. Mr. Hall then read notes of six cases in which the instrument had been of the greatest benefit. He had always found it thoroughly trustworthy; he questioned whether such perfect separation could be obtained as absolutely to exclude minute contamination of urinary specimens obtained from each kidney but this had little, if any, practical significance.—Dr. W. E. Heilborn read notes of a case of Intestinal Obstruction caused by a Gall-stone with spontaneous recovery. The patient was a woman, aged 64 years, with no history of any previous attacks of gall-stone colic or jaundice. When first seen there had been absolute obstruction for four days, vomiting, dry brown tongue, a pulse-rate

of 120, and a distended abdomen. Operation was refused. After four enemata she passed a gall-stone of the size of a large pigeon's egg. Recovery was rapid and complete.

HARVEIAN SOCIETY.—A clinical meeting of this society was held on Jan. 25th.—Dr. Alexander Morison showed a case of Endocarditis in a Child associated with Chorea.—Dr. L. G. Guthrie showed a case of Gumma Cerebri. The patient, a man, aged 29 years, was admitted to hospital on Oct. 24th, 1905, with right-sided hemi-paresis and double optic neuritis. Seven years previously he contracted syphilis, for which he was under treatment for three months. There were no obvious secondary symptoms but his health had never been good since. He complained of "general deterioration, mental and physical." 15 months previously he noticed gradual weakness of the right arm and leg which increased until he had to give up employment owing to inability to write or to hold his pen properly. There had been slight headaches at times but no vomiting. After admission the optic neuritis and contraction of the visual fields increased. On Nov. 3rd a slight epileptiform seizure occurred with general convulsions and loss of consciousness but no focal commencement; its duration was about ten minutes. On the 8th he had two more attacks in which he became dazed and stupid but without loss of consciousness. He had had no fits before or since. He was treated by iodides which were pushed, until by mid-December he was taking 50 grains of mixed iodides thrice daily. The swelling of the left disc then began to subside, that on the right remaining *in statu quo*. He had slight iodism, soreness of the eyelids, and a few spots. The iodides were then gradually reduced to 24 grains of mixed salts thrice daily. The patient had improved in general health and had gained weight. The hand movements had become less ataxic under treatment by exercises. He could now write fairly well though slowly. The gait was less spastic. The diagnosis was gumma, probably supracortical, in the mid-area of the left cerebral hemisphere.—Dr. Squire showed a case of Leontiasis Ossea in a woman, aged 29 years. There had been proptosis and deformity of the forehead from birth. Blindness of the right eye was first noticed at the age of nine years. The forehead was large and there was a marked bony protuberance at the site of the anterior fontanelle. The nasal bones were thickened and the septum was deflected.—Dr. Guthrie suggested that the malformation was a congenital deformity due to premature synostosis of certain cranial sutures rather than one caused by leontiasis ossea.—Dr. E. Cantley agreed with Dr. Guthrie that the case was one of "tower shaped" skull due to congenital malformation.—Other cases were shown by Mr. T. Crisp English, Mr. E. Laming Evans, and Dr. J. F. H. Broadbent.

A NEW ASYLUM FOR IDIOTS.—At the meeting of the Gloucester city council held on Jan. 24th it was decided to unite with the Gloucestershire county council and other local authorities in leasing and adapting Sandwell Hall, Birmingham, as an asylum for idiot and imbecile children, the city and county together to acquire 20 beds.

INSTITUTE OF CHEMISTRY OF GREAT BRITAIN AND IRELAND.—The following is the pass list of the examinations held in January:—Of 14 candidates who entered for the intermediate examination, ten passed: A. P. Davson, F. W. Foreman, W. Garsed, T. R. Hodgson, B.A. Cantab., T. J. Kirkland, A. Lathwood, B.Sc. Lond., B. D. W. Luff, J. F. Reid, H. Stanley, B.Sc. Lond., and F. Tattersfield. In the final examination for the Associateship (A.I.C.), of five examined in the branch of mineral chemistry, two passed: E. R. Ballock, Assoc. R.O.Sc. Lond., and T. F. Cowle; of four in metallurgical chemistry, two passed: H. J. B. Rawlins, B.Sc. Lond., and Thomas Stenhouse, B.Sc. Lond., Assoc. R.O.Sc. Lond., A.R.S.M.; of four in organic chemistry, three passed: W. P. Hayworth, F. H. G. Horsman, B.Sc. Lond., and D. Spence, Ph.D. Jena; and of 112 who entered in the branch of the analysis of food and drugs and of water, including an examination in therapeutics, pharmacology, and microscopy, the following nine passed: J. T. Cart, B.Sc. Lond., C. G. Gates, B.Sc. Lond., A. G. Holborow, Miss E. S. Hooper, B.Sc. Lond., S. J. Lewis, B.Sc. Lond., A. J. C. Lickorish, S. G. Liveredge, Miss E. A. Macadam, and F. E. Thompson, Assoc. R.O.Sc. Lond.

from the neighbouring healthy skin, and transparent, so that the delicate underlying blood-vessels were clearly visible. The infant was born dead at full term. Microscopical examination of sections showed that the defect consisted of a complete arrest of development of all layers of the epidermis, including its associated glands and hairs. The cutis vera was unaffected except, of course, in so far as it lacked hair follicles and sweat and sebaceous glands.

CORK MEDICAL AND SURGICAL SOCIETY.—A meeting of this society was held on Jan. 24th, Dr. C. Y. Pearson being in the chair.—Dr. W. E. A. Cummins showed a Cystic Tumour removed from a married woman two months after the birth of her second child. She had noticed it at the age of 14 years; it gradually increased and when she was admitted to hospital it was found to extend from the right iliac region to the under surface of the liver and well to the left side of the middle line. He diagnosed a cyst of the broad ligament on the right side and opened the abdomen by a median incision, finding transverse vessels, evidently renal, running into the tumour. These he ligatured and had no trouble in removing the growth, which was intimately united to the kidney. The latter was also ablated. He packed the huge cavity with gauze and the patient made an uneventful recovery.—Dr. A. E. Moore reported on the specimen, which he considered due to an error of development—namely, to persistence of a portion of the Wolffian body. In this case the capsule was split to inclose the kidney. He demonstrated the normal ureter, thus excluding the existence of hydronephrosis.—Dr. Pearson said that it was a unique case and agreed with Dr. Moore's theory of the origin of the tumour; he questioned the necessity for abating the kidney but thought that he would have done the same in like circumstances.—Dr. Pearson showed a specimen of Tuberculous Kidney and Ureter removed from a woman with a history of pyuria. The cystoscope showed no cystitis. Luys' segregator was used and the healthy urine was found to show a daily excretion of 300 grains of urea, an amount which he considered satisfactory. In operating he made the usual "Kelly" incision. He found considerable enlargement of the kidney with evidence of much perinephritis and great thickening of the ureter, which latter he clamped and ligatured as low down as possible. The renal vessels he clamped, leaving the forceps *in situ* for a couple of days. Post-operative vomiting, as usual in these cases, was very troublesome. He thought that the invasion of the kidney was primary in this case.

ROYAL ACADEMY OF MEDICINE IN IRELAND: SECTION OF SURGERY.—A meeting of this section was held on Jan. 12th, Sir Arthur O'Hance, the President, being in the chair.—Mr. R. Charles B. Maunsell read a paper entitled "Remarks on Gastro-enterostomy, with description of a New Clamp." He advocated operation in gastropexia and atonic gastritis in addition to the more commonly recognised indications. He considered that there should be no fixed rule for the site or form of incision in the abdominal wall or for the site of junction of the viscera, as the first would depend upon the amount of ptosis present, often lying partly below the level of the umbilicus on the left side, the junction of the viscera being made near the pyloric antrum or at the most dependent portion of the stomach, according to the amount of muscular power present in the stomach walls. A new form of clamp was described and shown; it was made somewhat on the principles of Carwardine's intestinal clamp and held the parts neatly in position during the operation.—The President expressed himself in favour of clamps and recognised the advantages of those designed by Mr. Maunsell.—Mr. A. J. M. Blayney said that he was not in favour of clamps as he considered that their use increased the risk of post-operative hæmorrhage. He had not known of any case in which dispensing with clamps had led to any untoward result through escape of stomach contents or prolongation of the operation.—Mr. G. Jameson Johnston said that he was in favour of clamps and had not noted hæmorrhage in any of his cases.—Mr. William Taylor read a paper on Partial Gastrectomy for Pyloric Tumour. The patient, a woman aged 60 years, was exhibited in perfect health, free from stomach trouble of any description, and able to eat anything and everything without the slightest discomfort. The history dated back for three years, during two and three-quarter years of which she complained of ill-defined stomach trouble, to which she applied the term

"weakness." During the last three months of this period she was never free from pain but food greatly aggravated it. At times it was so severe as to compel her to press her stomach across the back of a chair or the edge of a table; at other times she rolled upon the floor in agony. A tumour afterwards formed which increased very rapidly in size and it was on account of this tumour and the severe pain and vomiting that she sought admission to hospital. On examination the tumour was found to be situated a little above, and to the right of, the umbilicus; it was hard, nodular, and firmly fixed to the anterior abdominal wall. There was no tenderness. The stomach was moderately dilated. The patient herself was greatly emaciated. Examination of the gastric juice showed a complete absence of free hydrochloric acid. The diagnosis of malignant disease was made. Exploratory laparotomy was performed, when it was discovered that by excising the portion of the abdominal wall to which the tumour was adherent the growth could easily be brought outside. This was accordingly done, and as the tumour presented all the naked-eye appearances of malignancy a partial gastrectomy was performed. The cut ends of the stomach were sewn up with two rows of silk sutures. The duodenum was freed by dividing the peritoneum over the right kidney and fixed by two rows of suture into the opening made into the posterior wall of the stomach, about one inch beyond the line of section. The entire operation occupied exactly 70 minutes and the shock was very slight. Recovery was rapid and uninterrupted and the patient left for the convalescent home on the twenty-third day after the operation. Examination of the gastric juice on that day (Jan. 12th), seven months after the operation, showed that there was not a trace of free hydrochloric acid, or, indeed, of any other free acid to be found. The pathological report described the tumour as apparently a mass of inflammatory material deposited around an old-standing ulcer.

BRISTOL MEDICO CHIRURGICAL SOCIETY.—A meeting of this society was held on Jan. 10th, Mr. John Dacre being in the chair.—Mr. Harold F. Mole gave a demonstration on the anatomy and surgical anatomy of the temporal bone illustrated by a large number of lantern slides, stereograms, and specimens. The latter consisted of preparations of the bone and metal corrosion casts of the same. Great stress was laid on the importance of surgeons operating on the ear having an accurate knowledge of important structures in relation with it and the specimens were specially prepared to show these relationships. One series of bones showed the various steps in the complete mastoid operation; another series, after the radical mastoid operation had been performed, were sectioned in various planes to show the relation of the facial canal to the operation area; a third were sectioned to show the relation of the lateral sinus to the antrum; another to show the depth of the antrum from the surface and the value of Henle's spine and the suprasternal triangle as a guide to the antrum, &c. The corrosion casts showed the intimate connexion of the tympanic cavity with the cells of the mastoid process and those outside it and above the external auditory meatus. Some of them showed a mass of cells at the apex of the petrous bone not usually described in text-books of anatomy.—Dr. P. Watson Williams and Dr. J. Lacy Firth congratulated Mr. Mole on the preparations.—Dr. Watson Williams read a paper entitled "Why Defective Nasal Respiration Impedes Growth and Development," emphasising the view that defective nasal breathing was not always due to, or in direct proportion to, the degree of nasal obstruction. Normal nasal breathing stimulated the bulbular respiratory centre and the abrogation of this physiological stimulation was one important factor resulting in deficient respiratory exchanges and consequent defective tissue metabolism. Hence the mechanical obstruction to respiration was by no means the only indication for appropriate treatment.—Dr. R. Shingleton Smith, Dr. E. O. Williams, Dr. A. J. Harrison, and Mr. Mole took part in a discussion on the paper, agreeing with Dr. Watson Williams on the importance of removing nasal obstructions in childhood and that the nasal obstruction was not always due to adenoids.—Dr. H. G. Kyle read notes of a case of Hydatid Cyst of the Liver occurring in a woman, aged 25 years. The tumour had attained very large dimensions, displacing the heart upwards, so that the maximum impulse was in the third left space, the lower limit of the tumour being about on the level of the umbilicus. It grew in the left lobe of the liver. It was treated by incision, removal of the hydatid membrane, and drainage. The patient made a good recovery. Dr. Kyle discussed the propriety of attempting

Information will be derived from a study of its contents. Some of the chapters, however, are rather too curtailed, as, for instance, the one dealing with mitral insufficiency. But, as a rule, the subject matter is dealt with in a thoroughly practical and praiseworthy manner.

The National Standard Dispensatory. By HOBART AMORY HARE, B.Sc., M.D.; CHARLES CASPARI, jun., Ph.G., Ph.D.; HENRY H. RUSBY, M.D.; JOSEPH F. GEISLER, Ph.C.; EDWARD KREMERS, Ph.D.; and DANIEL BASE, Ph.D. London: J. and A. Churchill. 1905. Pp. 1860. Price 31s. 6d. net.

THIS colossal compilation might be well described as an encyclopædia of modern pharmacology and pharmacy. It contains between its covers 1860 closely printed pages and the size of the volume is somewhat larger than the new Medical Directory. It deals with the natural history, chemistry, pharmacy, actions, and uses of medicines, including those recognised in the pharmacopœias of the United States, Great Britain, and Germany, and besides there are numerous references to other pharmacopœias. Needless to state, the subject matter is in accordance with the eighth decennial revision of the United States Pharmacopœia of 1905. If it were otherwise its *raison d'être* would be gone. The work, in fact, which has been printed in America, is designed to succeed the National Dispensatory of Stillé and Maisch, which for years was recognised as a standard work of reference on pharmacology. 'The merest glance through the pages shows the earnestness and care with which its compilers have done their work.' No pains have been spared to bring the work into accord with modern knowledge, with the result that the book is certain to secure a place as a valuable source of reference on pharmaceutical matters. The considerable advances which have been made during recent years have entailed, as will be easily understood, a considerable amount of work in order to render the subject-matter of value to the modern reader and this work has been increased by the attention which has been given to remedies which are not universally known and which, in fact, have gained, so to speak, a local reputation—remedies which for this reason will not be found mentioned in general contributions on the subject.

One excellent feature of the work is the thoroughness with which what may be described as the assay section of pharmacy has been done. We regard this feature as of particular value because on these questions there is necessarily very little practical information in the official compilations that can guide the pharmacist. Thus references to the properties and tests of the drugs and chemicals described constitute, in our opinion, a very valuable source of reference in the work, especially as the facts concerned are drawn from the chief foreign pharmacopœias. The sections on alkaloids and volatile oils are most thoroughly treated; the latter section, perhaps, receives the greater share of space and in it is included a valuable table of constituents and physical constants. Radium takes its place in the pharmacological list and the account is excellent while not lengthy, the description of the events which led to its discovery being most intelligently and tersely written. While this is so we may express some surprise at not finding in the article on mineral waters any reference to the radio-active property which is now known to characterise so many of them and from which it would appear that they derive some of their therapeutic effects. We read, for instance, that the waters of most of the thermal springs do not possess any therapeutic properties apart from their heat. This statement, we imagine, must now be modified in view of the radio-active property which marks almost all thermal waters and in this connexion may be mentioned the waters of Bath and Buxton.

Considering the enormous amount of exact work which

has been done in this country owing to the epidemic of poisoning by arsenical beer a few years ago, we should have thought that the article dealing with the detection of arsenic would have been in a closer line with these modern investigations than it is. The old classical tests for arsenic are known to present certain fallacies and it is of the utmost importance that they should be observed in toxicological practice. Owing to the special attention which was forced upon chemists and others in this country we doubt whether the subject is anywhere so far advanced as it is at the present time in England. In the article on amyl alcohol it is stated that small amounts of this alcohol are nearly always present in ethyl alcohol and in all compounds containing the latter. Later it is remarked that this is especially true in regard to freshly distilled or raw preparations. As a matter of fact, amyl alcohol is not eliminated in potable spirits by age at all events, as a higher proportion is invariably found in old whisky or brandy than in the freshly distilled product. Whisky, it is remarked, is more easily obtained unadulterated than is brandy, and for this reason, the writer states, is preferred for most medicinal purposes. Therapeutically, we hold, the two cannot be regarded as interchangeable, assuming that they are genuine. The disagreeable odour of raw whisky is stated to be due to a small quantity of amylic alcohol, which on keeping is changed into an ether and perhaps partly into valerianic acid. This can hardly be the case in view of what we have already said.

The appendix will be a useful guide to the pharmacist who wishes to turn analysis to account in the examination of drugs, while the article on the physiological testing of drugs, including suprarenal extract, will be read with profit because of its practical character. The index is admirably drawn up and comprehensive and is divided into a general index of over 100 pages and a therapeutic index of 20 pages. The printing of the words fluid ounce, fluid drachm, and fluid extract as fluidounce, fluidrachm, and fluidextract is open to objection.

To say that the work is practically a complete storehouse of modern pharmacological and pharmaceutical knowledge is no exaggeration and the editors may be congratulated on the success with which they have accomplished a very great task. The names of the distinguished American professors of therapeutics, materia medica, pharmacy, botany, and chemistry (in its various departments) on the title-page are calculated to assure the reader of the trustworthy character of the mass of information contained in the volume.

Das Biologische Verfahren zur Erkennung und Unterscheidung von Menschen- und Tierblut. (The Biological Method by which the Blood of Man and of Beasts may be Recognised and Distinguished.) By Professor UHLENHUTH. Jena: Gustav Fischer. 1905. Pp. 152. Price 3 marks.

This little volume contains a collection of short articles published at various times in the medical journals by Professor Uhlenhuth on the biological tests for blood. The principle on which these tests are founded is now generally accepted—namely, that the serum from an animal which has been injected by way of the peritoneum with any given organic fluid will, if mixed in small quantity with a dilute solution of the fluid used for the injection, produce a more or less definite precipitate. For instance, if human defibrinated blood be injected into the peritoneal cavity of a rabbit the serum obtained from the rabbit's blood, when mixed with a clear solution of the blood of man, will produce a precipitate and agglutinate the red blood corpuscles if present. A similar reaction will not follow if such serum be added to a solution of the blood of any other animal. Professor Uhlenhuth speaks in the highest praise of the value of this test in medico-legal practice and maintains that it may be

Reviews and Notices of Books.

The Medical Epitome Series. Edited by V. O. PEDERSEN, A.M., M.D., Instructor in Surgery at the New York Polyclinic Medical School and Hospital; Genito-Urinary Surgeon to the Out-Patient Department of the New York Hospital; Physician-in-Charge of St. Chrysostom's Dispensary, &c. 16 vols. London: Hodder and Stoughton. Price 4s. each.

Messrs. Hodder and Stoughton have issued a series of 16 volumes known as "The Medical Epitome Series" under the editorship of Dr. V. O. Pedersen. The volumes deal with most of the departments of medical teaching.

In arranging for the editorship of the series the publishers established the following condition—namely, that the series, as a whole, should embrace the entire realm of medicine; that the individual volumes should authoritatively cover their respective subjects in all essentials; and that the maximum amount of information, in letterpress and engraving, should be given for a minimum price. The volumes are well edited and are very creditable to the publishers as books. When we turn to the subject-matter in each volume, while we admit the evident care with which each is written, we cannot help feeling that the compression which has been necessitated in order to carry out the idea of uniformity in the series goes some way to lessen the value of many of the books. The question naturally arises as to what class of student or medical man would be content with such manuals and we are forced to admit that we think it would not be a high one.

The volumes may be divided into two classes—those which treat of purely clinical subjects and those which deal with the earlier subjects in a medical curriculum. It appears to us that the manuals for younger students are more valuable than those intended for the more advanced ones. For instance, if we take the volume on Surgery, which is said to be "a manual for students and practitioners," we find that the joint authors attempt to deal with the subject in a small book of 295 pages. The authors are brave men. After a careful study of the volume we admit that the subject-matter is excellent so far as it goes and that the illustrations are beyond praise, and yet we do not know the kind of professional man to whom such a work would permanently appeal or who would be satisfied with it. The book is too much advanced to be regarded as a book on first aid; it is not intended to be a work on minor surgery, for the graver surgical conditions are many of them rather fully considered; for instance, to such a disease as appendicitis five pages out of the small sum-total are devoted; and yet no student or practitioner could possibly be satisfied to make this work his text-book of surgery, for many conditions are merely touched upon; the novice would not understand—he cannot read between the lines, the qualified man requires many more details. It appears to us that the only man to whom the book could really be useful is one who wants to take a general survey of his surgical work during the last few days before an examination for one of the minor surgical qualifications.

In the volume on Obstetrics the information is sound as far as it goes and the illustrations of the application of the forceps are particularly good. The authors of the volume on the Diseases of the Eye and Ear make no reference to auditory or aural vertigo under the name of Ménière's disease, though vertigo is alluded to as a symptom under diseases of the internal ear. In the volume on Diseases of the Skin an alphabetical arrangement of the diseases is given in order to facilitate reference, and because, as the author reminds us, the present classification of the cutaneous disorders from the standpoint of pathology is by no

means final. The volume on Anatomy runs to 389 pages of a print which is smaller than that contained in most of the volumes; it is a systematic work and not a companion for the dissecting room. Physiology is considered in a book of 255 pages; all the essential facts with which the student and practitioner should be familiar appear to be gathered together in this manual. In the volume on Normal Histology the intention of the writer has been to tabulate clearly and concisely the most important points; sufficient embryology is included to aid in a correct understanding of histology and a better appreciation of pathological processes. In the volume on Chemistry and Physics the purpose has been to set forth accepted and proved facts forming the basis of the sciences in a manner which, in the author's opinion, will serve best for their clear and easy understanding by the student. In each volume the chapters are succeeded by a number of questions on the subject-matter which will be useful in enabling students to review their knowledge when preparing for examinations.

The subject-matter of the volumes appears to us to be accurate, clear, and up to date, and the cardinal facts are ably set forth. The danger of a series of books of this kind lies, in our opinion, in the possibility that some classes of students may accept these volumes not merely as being of service in laying a foundation to their knowledge but as substitutes for the larger text-books. The books contain essentials but there is no room in them for explanations.

Diseases of the Heart and Aorta. By THOMAS E. SATTERTHWAITE, M.D., Professor of Medicine in the New York Post-Graduate Medical School; Consulting Physician to the Post-Graduate Orthopædic and Babies Hospital. New York: E. R. Pelton. Pp. 304.

THIS volume is based on a series of articles which originally appeared in medical periodicals; the whole contents of the work, however, have been carefully revised, so that much new matter has been added since the communications were first published. The aim of Dr. Satterthwaite has been to try to place before the general practitioner a brief, simple, but practical consideration of the affections of the heart and of the aorta. Most of the conclusions have been arrived at from the personal experience of the author and the whole character of the volume is essentially practical. Little space is given to the anatomy or the surgery of the heart and large blood-vessels, congenital anomalies and neoplasms of the heart are only briefly referred to in the appendix, and the subject of parasites affecting the heart is disposed of in about 15 lines. Theories and methods of treatment which are of interest mainly from a historical point of view receive but scant notice, as they are not of practical interest. Only brief mention, too, is made of the sphygmograph, as Dr. Satterthwaite believes that the use of this instrument is likely to mislead rather than to help at the bedside or in the consulting room. The practical value of the sphygmomanometer is, however, recognised.

Much stress is laid on the comparative value of diagnostic signs and the relative frequency and gravity of the various valvular lesions are referred to at length. After due consideration of the prognosis of affections of the valves of the heart Dr. Satterthwaite places the lesions in the following order as regards gravity, the most grave standing first: (1) mitral stenosis; (2) aortic insufficiency; (3) aortic obstruction; and (4) mitral insufficiency. This conclusion is arrived at by estimating the average age at death of patients suffering from the respective lesions. Authorities are not unanimous on this point but the above order is the one now accepted by some of the larger assurance societies. Many observers, however, still maintain that aortic insufficiency must be considered more dangerous than mitral stenosis and aortic obstruction as less serious than mitral insufficiency.

Taking the book as a whole, we consider that much useful

surprised to find that St. Bartholomew's Hospital is indexed as "Bartholomew's (St.)" under the letter "B," while St. George's, St. Mary's, and St. Thomas's hospitals appear under the letter "S."

Pannell's Reference Book for Home and Office. London: The Granville Press, Limited. 1905. Pp. 984. Price 6s. 6d.—This volume contains a large amount of valuable and useful information. It is arranged according to the following divisions: an English dictionary, aids to the study of English, a dictionary of general information, a medical dictionary, a guide to education and the professions, a social guide, the world and the empire, a legal guide, and a commercial guide. As a general book of reference it will be found very convenient as it contains many matters which are of interest to everybody. We cannot commend the idea of a "medical dictionary" intended for the use of the public. In this instance, however, the author of this section has succeeded in giving information which will be generally instructive without entering upon matters which concern a medical practitioner only. In fact, the author's intention has been well carried out. In the preface he explains that he wishes to offer "a few remarks to serve as a finger-post in directing the reader to the right use of this dictionary of medicine, which is not intended to supersede the doctor but to indicate when he should be called in and to act as a guide in emergencies when he is not immediately available, or in simple cases when his aid is not needed." The author further says that he has aimed at making this dictionary a "guide to health." He gives some sound advice as regards domestic and general hygiene but carefully avoids giving any directions as regards drug treatment which could only be carried out under the directions of a medical man. The section on "General Information" deals with an immense variety of matters, from the names most frequently occurring in current literature to the distinguishing letters on motor-cars.

The Royal London Ophthalmic Hospital Reports. Edited by WILLIAM LANG, F.R.C.S. Eng. Vol. XVI., Part III., October, 1905. London: J. and A. Churchill. Pp. 209. Price 5s.—This part of the Royal London Ophthalmic Hospital Reports contains eight articles, all of which are of interest. The first is by Mr. E. Nettleship and deals with the subject of heredity in the various forms of cataract. He recognises two principal classes, acquired or postnatal and congenital cataract. The congenital is subdivided into lamellar, the much less common axial or spindle form, and complete cataract. A considerable number of cases have been collected by Mr. Nettleship, many from his own practice and many from journals, theses, and other sources in which the heredity is clearly shown by genealogical tables. One remarkable case is that of a family in which five generations present a total of 30 cases of cataract in 90 persons. A good bibliography is appended to the article. Mr. E. Treacher Collins has a communication on Capsular Complications after Cataract Operations. In some instances the complications resulted from adhesion of the lens capsule to the extraction scar, either becoming entangled in the wound or adherent to the back of the wound; in other instances the complications resulted from opacity occurring in connexion with the lens capsule after extraction of cataract. Examination with the microscope showed in different cases retained lens substance, wrinkling of the anterior capsule and new growth of cells lining it, and adventitious fibrous tissue. Three plates accompany this article. Mr. George Coats gives an account of a case of Obstruction of the Central Artery of the Retina. This article is illustrated by three plates showing sections of the obliterated artery. Mr. Angus MacNab describes Marginal Blepharitis, its Cause, Pathology, and Treatment. He finds that the majority of cases have the Morax-Axenfeld bacillus in the secretions. The treatment

by the use of sulphate of zinc gives the best results. Mr. M. S. Mayon contributes an article on Implantation Dermoids of the Conjunctiva, illustrated with one plate. Glioma Retinae is a reprint of a thesis by Dr. S. A. Owen, read for the M.B. degree before the University of Cambridge. The two remaining articles are on Papilloma Limbi Conjunctivæ, by C. Pascheff, M.D., of Sofia, Bulgaria, with two plates, and a Case of Tubercle of the Nerve Head, by Mr. G. Coats, with a plate.

The Englishwoman's Year-Book, 1906. Edited by EMILY JAMES. London: Adam and Charles Black. Pp. 402. Price 2s. 6d. net.—This year-book will be found of the utmost value to any woman who is thinking of taking up any employment, in whatever class of life she may be in. It is full of information and seems to us to be most carefully edited. We see that the work is in its twenty-sixth year of issue and it is curious to compare the variety of occupations in which women are now engaged with those open to them a very few years before the first issue of the year-book in question.

The Schoolmaster's Year-Book and Directory, 1906. London: Swan Sonnenschein and Co., Limited. Pp. 562. Price 6s. net.—This work may best be described to our readers as being, *mutatis mutandis*, the schoolmaster's "Medical Directory"—that is to say, it gives much the same information to schoolmasters and others connected with the teaching profession as does the Medical Directory to medical men. The introductory review of the year is somewhat pessimistic in tone, for the author says: "We have neither the schools, nor the men, nor the money." We feel inclined to add "nor the grammar" which we trust the schoolmasters will not endorse.

"*Porte-vous bien?*" By Dr. TERWAGNE. Third edition. Paris: Vigot Frères. 1905. Pp. 115. Price francs 1.50.—This is an excellent little brochure giving popular and rational elementary views about hygiene by a medical man who is a communal councillor of Antwerp and vice-president of the league against tuberculosis. Anyone who will read it and follow its practical suggestions will be able "to carry himself well"—i.e., to keep in good health without the aid of physicians or druggists. The author is a very self-denying medical man who shows his clients how to do without him and his services. The opusculum gives short, concise talks on air, light, water, foods, sleep, trade or profession, work, tobacco, the temperaments, and, lastly, health, which is "le seul capital indispensable."

A Treatise on the Parasites and Parasitic Diseases of the Domesticated Animals. By Professor NEUMANN of Toulouse. Translated by GEORGE FLEMING, C.B., LL.D., F.R.C.V.S. Second edition, revised and edited by Professor MACQUEEN F.R.C.V.S. With 265 illustrations. London: Baillière, Tindall, and Cox. Pp. 957. Price 21s. net.—There is no book in the English language which deals with the parasitic diseases of the domesticated animals so fully as the late Dr. Fleming's translation of Professor Neumann's work; and the second edition has been in every way completely revised and brought up to date by Professor Macqueen. It is a standard authority and deals not only with the transmissibility of the parasitic diseases from animal to animal but also from the lower animals to man; and for the student of comparative parasitology, whether he is a medical or a veterinary practitioner, every page contains something of interest. It is a book which should find a place in every medical library and on the book-shelves of every specialist in skin diseases and of every medical officer of health.

JOURNALS AND MAGAZINES.

The Journal of Physiology. Edited by Sir MICHAEL FOSTER, K.C.B., F.R.S., and J. N. LANGLEY, Sc.D., F.R.S. Vol. XXXIII. Nos. 4 and 5. London: C. J. Clay

absolutely relied upon. Among the drawbacks to the biological test are its intricate technique and the long experience that is required before trustworthy results can be obtained. Professor Uhlenhuth admits this difficulty and with a view of rendering aid to those practitioners who may wish to employ these tests he has made this collection of the numerous articles which he has written on the subject. This entails a certain amount of overlapping in the various chapters but in dealing with a difficult and important subject repetition is not a serious fault.

Various other albuminous substances which may be encountered in medico-legal practice, such as stains of seminal fluid, are also referred to and it is explained how biological tests may be of value when such examinations have to be made. This book will be found of considerable value to those who are interested in forensic medicine.

Handatlas der Operationen am Schläfenbein, für Aerzte und Studierende, insbesondere für angehende Spezialärzte. (Hand Atlas of Operations upon the Temporal Bone, for Physicians and Students, especially for those commencing to Specialise.) By Professor GERBER of Königsberg, Prussia. With ten tables and nine plates in the text. Wiesbaden: J. F. Bergmann; Glasgow: F. Bauermeister. 1904. Pp. 46. Price 8s.

THE hand atlas of Professor Gerber is intended largely as a means of enabling practitioners to have within their reach a lucid and illustrated description of those operations which are connected with diseases of the ear, so that those who are unable to have access either to anatomical preparations or to skilled assistance may be able to relieve those of their patients who are suffering from any aural disease necessitating operation.

The first division of the work deals with the complications of suppurative otitis demanding operation and the operation indicated for each complication. These details are given in a tabular form and are clear and concise. The directions with reference to the moment to be selected for operation are given in an extremely vague way, for Professor Gerber says that "when the critical moment has arrived, after conservative treatment has failed, then it is necessary to operate," although later this vague direction is somewhat more sharply defined. He then proceeds to describe, in the fewest possible words, the preparations for operation. The armamentarium of the surgeon is laid down with elaborate detail. Professor Gerber then deals with the post-aural operations, commencing with a general description, applicable to all, describing the ordinary semicircular incision, which commences above the auricle and terminates at the tip of the mastoid process. He then considers what he terms "the typical opening of the mastoid," but which is better known as the "Schwarze" operation. There is nothing whatever new in this but it is very clear. Professor Gerber next enumerates the various abnormalities which may interfere with the technique of the classical operation and then the method of opening the antrum in these unfavourable circumstances, as, for instance, in cases where the lateral sinus is very high up and far forward. Next comes the radical operation. This part of the work is divided into several sections and the classical operations of Zaufal and Stöcke are carefully portrayed. Professor Gerber next proceeds to treat briefly the plastic methods adopted when covering in the operation cavity partly or entirely with skin. He devotes considerable space to the after-treatment which is very carefully reviewed. A short account is given of the various methods of closing the retro-auricular openings, a procedure which, we are glad to say, is rarely required at the present time in this country. Next follows the operation

necessary for opening the labyrinth, followed by the procedure employed for dealing with the various collections of purulent material within the cranium, extradural, cerebral, and cerebellar. In a few words, meningitis serosa, lumbar puncture, puncture of the ventricle, purulent pachymeningitis, and leptomeningitis are dealt with. The letterpress concludes with the description of operations on the lateral sinus, ligature of the jugular vein, and the laying bare of the jugular bulb. Throughout Professor Gerber is unusually sparing in his words. They are clear and concise, though perhaps hardly sufficiently lucid really to enable surgeons not thoroughly conversant with the surgical anatomy of the part to work with any confidence, at any rate, in their earlier operations.

The plates are very admirable reproductions of operations performed on the cadaver; the first plate depicts the incision, the next the bone, with the soft parts retracted, one showing the opening in a case of simple disease of the antrum, and another that in a case of disease of the mastoid process. The next four drawings represent the second and third stages of a radical mastoid operation and the completed operation. Stöcke's operation comes next, together with three phases of one method of dealing with the external auditory meatus, and the only criticism which we wish to make on this is that the cutaneous surface appears to have been most obligingly elastic, more so we fear than will be found in practice. The fourth plate consists of two other methods of dealing with the external meatus and a method of applying the bandage. The fifth plate deals with the plastic methods of closing a post-auricular opening. Two figures in Plate VI. are devoted to the opening of the labyrinth and are relatively clear. In the other two figures in this plate the dura mater is exposed in the temporal fossa. In Plate VII. operations on the lateral sinus are depicted. Plate VIII. shows the dissection necessary for ligation of the jugular vein and the freeing of the bulb. In Plate IX. the dissection employed for laying bare the lateral sinus and the jugular vein in continuity is delineated. The last plate shows three anatomical figures, the soft parts having been removed, the first representing a radical operation on the tympanum; the second this combined with exposure of the facial nerve and jugular vein; and the third merely the removal of the front wall of the mastoid process.

Professor Gerber has already earned the gratitude of all rhinologists by the production of his "Atlas of Rhinology." The work at present under consideration, we regret to say, does not occupy relatively so high a position. It is, however, an extremely useful work and will be much appreciated by those for whom it is intended, the more so as its very moderate price will place it within the reach of all. It will be a most useful work in operations on the cadaver, for except under extraordinary conditions it cannot be desirable that a surgeon should work up overnight the technique of these operations, some of the most difficult in surgery, intending to employ them on the living subject the next day, for there probably exists no class of operation requiring greater experience and more skilful technique. However, as a guide to operative aural surgery, especially on the dead body, there certainly exists no better book.

LIBRARY TABLE.

Herbert Fry's Royal Guide to the London Charities. London: Chatto and Windus. 1906. Pp. 293. Price 1s. 6d.—This, the forty-second annual, issue of "Fry" is as useful as ever and forms an excellent guide for those who have money to dispose of for charitable purposes but are ignorant as to how they shall dispense it. We must draw the editor's attention to one irregularity. We naturally returned to the entries concerning the hospitals and we

Asphyxia, by Ivy McKenzie, M.A., M.B. Glasg. 6. On the Development of the Hind Brain of the Pig, by O. Charnock Bradley, M.B., D.Sc. Edin., with six plates. 7. A Study of the Astragalus, by R. B. Seymour Sewell, B.A. 8. The Arrangement of the Elastic Fibres in the Bronchi and Lung, by James Miller, D.Sc., M.D. Edin., with five illustrations in the text. 9. A New Method of Demonstrating the Topographical Anatomy of the Adult Human Skull, by Sydney R. Scott, M.B. Lond. 10. A Note upon the Mode of Termination of the Posterior Tibial Artery and Nerve, by Charles R. Whittaker, L.R.C.S. Edin., with three drawings in the text. This part also contains the Proceedings of the Anatomical Society of Great Britain and Ireland for August, 1905.

New Inventions.

IMPROVED GOUGE FOR MASTOID OPERATION.

IN the performance of the radical mastoid operation for suppurative disease of the middle ear I have found two instruments very useful. They are both modifications of those usually employed. The first is a quarter-inch gouge of very shallow curvature with square ends. The second is shaped like a carving chisel and its appearance is well shown in the accompanying illustration. This latter instrument is especially useful in removing the posterior wall of the meatus in young children, as only a very small portion of the cutting edge is used at one time.

Both instruments are made with Ballance's handles and they form part of a complete set which have been specially made for me by Messrs. Cuxson, Gerrard, and Co., Birmingham, with the handles all of uniform weight and size; this is a convenience in changing from one instrument to another.

A. KNYVETT GORDON,
Medical Superintendent, Mousall Hospital,
Manchester.

MOUTH PROPS FOR USE DURING SURGICAL ANÆSTHESIA.

HAVING up to recent times used solid vulcanite dental mouth props placed sideways between the teeth when it was necessary to keep them apart in certain cases of jaw spasm and obstruction to nasal breathing, I have lately devised an improved set of three hollow metal props which have a good deal of advantage over the other makeshift ones. Their superiority lies in the facts: (1) That they are sterilisable and indestructible by boiling or strong antiseptics; (2) that they allow of respiration when the jaws and lips are closed on and around them (a very important point in edentulous patients and people with full lips); and (3) that two of them are flattened at one end in order to make introduction easier during anaesthesia. The large one I usually place between the teeth before anaesthetising; big strong men, cases of intestinal obstruction with vomiting, and patients suffering from nasal obstruction, because it gives a very free way for air or fluid and keeps the jaws well apart; it is also intended

for use during narcosis of edentulous patients. The smallest prop may be useful in children. The illustrations will show the shape and relative size of the set of props. I am much

indebted to Messrs. Down Bros., of St. Thomas's-street, London, S.E., for the care and trouble which they have taken in carrying out my wishes in the matter.

W. J. MCCABDIE,
Anæsthetist to the General, Dental, and Ear
and Throat Hospitals, Birmingham.

THE EQUIPOISE COUCH COMPANY: A CORRECTION.

THE Equipoise Couch Company have pointed out to us that our description of the principle upon which the Equipoise Bed, Couch, and Chair works, as published in THE LANCET of Jan. 27th, is in certain respects not accurate. The principle on which these inventions work, and, indeed, upon which the main claim for novelty depends, has not, we admit, been made clear. And this principle is particularly ingenious.

All the articles are made in three parts, corresponding to the back, seat, and leg, and are connected by hinged joints. The novelty lies in the fact of the rear supports, or legs, being pivoted to the base and also to the back at the exact centre of equipoise, so that when in use the occupant can either remain level as in an ordinary bed or, if he so desire, he may, by merely bending the body at the hips, smoothly and easily raise himself

to the sitting or any intermediate position. As the back rises the seat declines at the back end, so that there is no tendency for the patient to slip towards the foot of the bed, as undoubtedly often happens when bed-rests are used, or merely supporting pillows. The leg part of the Equipoise couches is arranged to remain on the level or to decline in unison with the movement of the back, so that a change of position, often most grateful to the invalid, can be assumed for any purpose at any time. The patient merely releases a catch and the balance principle does the work. The new illustration shows the ease with which an Equipoise Bed can be raised or lowered; the child represented is moving the bed with one finger only, a point which will particularly appeal to those nursing heavy and helpless invalids. The bed can be locked securely in any position by depressing a handle, one of which will be found in a convenient position on either side of the bed. We recommend our readers to inspect the productions of the Equipoise Couch Company at the Institute of Hygiene.

A CONSCIENTIOUS OBJECTION TO VACCINATION.—At Brixham, Devon, on Jan. 26th, a stonemason applied for a vaccination exemption order chiefly on the ground that, being a vegetarian, he did not wish to have "animal matter" introduced into his child's system. The exemption was eventually granted, although one of the magistrates (Lord Clouston) strongly urged the applicant to have his child vaccinated.

and Sons. Pp. 187. Price 11s.—The following articles are contained in this number of the *Journal of Physiology*: 1 Colloidal Solution: the Globulins, by W. B. Hardy, Fellow of Gonville and Caius College, Cambridge, with 10 figures in the text. This is a long and important article. It deals with the behaviour of globulins to acids, alkalies, and salts, and the properties of the solutions considered as cases of colloidal solution. 2. Globulin, by J. Mellanby, with 16 figures in the text. Mr. Mellanby gives the following summary of the results that he has obtained: (1) Solution of globulin by a neutral salt is due to forces exerted by its free ions. Ions with equal valencies, whether positive or negative, are equally efficient and the efficiencies of ions of different valencies are directly proportional to the squares of their valencies. (2) The amount of globulin dissolved by a given percentage of neutral salt is directly proportional to the strength of the original globulin suspension. (3) The precipitation of globulin from solution in neutral salts by neutral salts depends upon a molecular combination between the salt and globulin, the compound so formed being stable only in excess of the combining salt. Precipitation by salts of the heavy metals depends upon the formation of a stable salt globulin compound. (4) Solution of globulin by acids or alkalies is of the nature of a chemical combination. The relative solvent efficiencies of strong acids and alkalies are of the same orders as their chemical avidities. 3. On the Reaction of Cells and of Nerve Endings to Certain Poisons chiefly as regards the Reaction of Striated Muscle to Nicotine and to Curari, by J. N. Langley, professor of physiology in the University of Cambridge, with eight figures in the text. Professor Langley concludes from his experiments that in all cells two constituents at least must be distinguished: (1) substance concerned with carrying out the chief functions of the cells, such as contraction, secretion, and the formation of special metabolic products; and (2) receptive substances especially liable to change and capable of setting the chief substance in action. Further, that nicotine, curari, atropine, pilocarpine, strychnine, and most other alkaloids, as well as the effective material of internal secretions, produce their effects by combining with the receptive substance and not by an action on axon endings if these are present or by a direct action on the chief substance. 4. The Paralysis of Involuntary Muscle, Part 3, on the Action of Pilocarpine, Physostigmine, and Atropine upon the Paralyzed Iris, by Dr. H. K. Anderson, with three figures in the text. This number also contains the Proceedings of the Physiological Society, Nov. 11th, 1905.

Medical Electrolgy and Radiology.—In the December number of this journal Dr. E. Reginald Morton contributes a paper on the Measurement of the Current passing through an X Ray Tube. The interesting feature of this is the employment of the oscillograph vacuum tube of Ruhmer, by which, under suitable conditions, the curve of the current traversing the tube can be observed directly. This tube is one of the most interesting instruments that has recently been brought out and since it can be used as a milliampèremeter as well as an oscillograph it will in all probability become very popular among the users of high tension and variable currents.

The Archives of the Rontgen Ray.—In the number for January Dr. Ernest Kingscote has an interesting note on the Diagnostic Value of the Roentgen Ray for the Soft Organs of the Body. The case in question had been successively diagnosed as one of aneurysm, new growth, and floating kidney. A skiagraph revealed a dilated heart pushing the diaphragm downwards towards the umbilicus in a wedge-shaped depression and the organ appeared to be dragging on the ascending aorta.

Three months after a six weeks' course of the Schott-Nauheim treatment the patient was very much better and the skiagraph showed that the heart had assumed the normal position. The case goes to show the importance of x ray examination in cases of the kind, since the ordinary methods of examination had revealed physical signs which were misleading. H. Guilleminot continues his paper on the Exploration of the Thorax by Orthodiagraphy, as also does H. E. Gamlen his Report on the General Utility of High-frequency Currents. With regard to the latter it is difficult to determine just how far the high-frequency currents have been responsible for the benefit accruing in some of the cases. The paper is interesting, however, and may be referred to with advantage. From the point of view of electro-physics the papers by Maurice Leblanc and William Rollins are very valuable contributions, both of them being continued from a previous number. The former, dealing with the Cooper Hewitt Mercury Vapour Lamp and Valve, shows how exceedingly useful this instrument may be both experimentally and commercially. It is here shown, among other things, that, contrary to the generally accepted opinion, a vacuum tube becomes a better conductor of electricity as the vacuum becomes higher. The future development and applications of the Cooper Hewitt lamp will be watched with great interest. Some excellent reproductions are given of radiographs of injected specimens made by A. G. Fryett of Melbourne and a very complete set of notes and abstracts assists to make up a very interesting number. We notice, however, that of the six original articles four are continued from previous issues and the two which are complete are very short. While quite appreciating editorial difficulties we cannot help thinking that the proportion of continued articles is rather large for a monthly journal.

Journal of Anatomy and Physiology. Conducted by Sir WILLIAM TURNER, K.C.B., F.R.S.; D. J. CUNNINGHAM, M.D., F.R.S.; G. S. HUNTINGTON, M.D.; A. MACALISTER, F.R.S.; and J. G. M'KENDRICK, F.R.S. Vol. XL. Third series. Volume I, Part II. With plates and illustrations in the text. London: Charles Griffin and Co. 1906. Pp. 102. Annual subscription one guinea.—The articles contained in this number of the *Journal of Anatomy and Physiology* are: 1. On the Fate of the Tænia Olinio orbitalis (Gaupp) in Echidna and in Ornithorhynchus respectively, with demonstration of specimens and stereo-photographs, by J. T. Wilson, M.B., C.M. Edin., professor of anatomy, University of Sydney, Sydney, New South Wales. This paper was read at the first International Federative Congress of Anatomy at Geneva in August, 1905. 2. Note on the Development of the Thymus Gland in Lepidosiren Paradoxa, by Thomas H. Bryce, M.A., M.D. Edin., a paper read at the first International Federative Congress of Anatomy at Geneva in August, 1905. Dr. Bryce has satisfied himself that the thymus in lepidosiren has up to an advanced larval stage absolutely nothing to do with the formation of the leucocytes. 3. Observations upon the Cetacean Flippers with special reference to Hyperphalangism and Polydactylism, by J. Symington, M.D. Edin., F.R.S. 4. Note on the Elastic Tissue in the Eye of Birds by E. W. Wace Oarlier, M.D. Edin., F.R.S. Edin. The birds examined and described in this paper are the house sparrow, chaffinch, goldfinch, skylark, swallow, blue tit, wren, wild duck, common gull, tern, and the budgerigar; bird's eyes contain a large quantity of elastic tissue and are provided with a special elastic tendon for the insertion of the ciliary muscle. In most birds the membrane of Descemet consists mainly of elastin and the pectinate fibres are chiefly composed of elastic tissue. The ciliary muscle invariably ends in a conspicuous bundle of rather coarse elastic fibres that bifurcate posteriorly, one portion being inserted into the choroid, the other portion into the perichondrium of the inner surface of the sclerotic cartilage. 5. Pulmonary Changes in

needed. The failure to do this may not often be discovered when the child recovers, but when death occurs a prosecution almost always is instituted which has a deterrent effect upon others. Whatever view, however, may be taken as to the desirability of legislative interference, it should, at any rate, be understood clearly that not a few deaths take place in the manner indicated, some of which are the result of deliberate crime, while all are preventable.

The Visit of the London County Councillors to Paris.

DURING the whole of next week the members of the London County Council will be enjoying the hospitality of the Paris Municipal Council. The reception promises to be most brilliant and cordial. Gala representations, both serious and of the light variety description, will enable the London county councillors to see how theatres and places of amusement are made to contribute to the maintenance of the Paris hospitals. The heartier the laughter, the more beautiful, attractive, and interesting the play, the larger the receipts for the relief of the poor and the suffering. Thus pleasure helps to relieve pain and sorrow and this in a very direct and material manner. Even the vice of gambling is utilised. Both the municipality and the Parliament have endeavoured to prevent horse-racing from degenerating into a mere pretext for gambling. "Bookmaking" has been suppressed by the strong arm of the law and the *pari-mutuel* substituted. But this State-controlled betting is only sanctioned on condition that a portion of every bet is handed over for the upkeep of the hospitals. If a person can afford to bet on a horse he can afford to subscribe to the hospitals and the law sees that such a contribution is duly deducted from the amount of the bet. Though the position of the general hospitals in London is, and we trust will remain, quite different, it will be interesting to our county councillors to see for themselves "how they manage these things in France."

Other objects of interest will be the *cantines scolaires* and the municipal bakery in the Rue Sipo where bread is produced for the 14,000 inmates of the Paris municipal hospitals. In regard to food-supply, the fact that there are no private slaughter-houses should be investigated. The great abattoirs at La Villette are not models of what a municipal slaughter-house should be, for they were built many years ago, but they are very much to be preferred to the numerous private slaughter-houses of the British metropolis. Also, though the *halles* do not possess the picturesque aspect of the old portion of Covent Garden Market, they are infinitely better suited to the needs of a great city. It will be interesting to compare the Parisian methods of inspection of meat and other alimentary substances with those in force in London, and to see how far the costermonger class are controlled so that they shall not sell that which is unfit for consumption. As regards matters relating to the drainage of private houses and to public sewers there is probably more to be learnt in London than in Paris, but the *casiers sanitaires des maisons* is a method of control which surpasses anything similar in England. It would be worth while for any town council to

go to Bordeaux¹ or to Paris if only for the sake of studying this method of keeping the record that builds up the complete sanitary history of every dwelling. Then again, in regard to the ventilation, the warming, and the application of the principle of unilateral light to the class-rooms of the Paris schools, there is a good deal worthy of observation. The ventilation of the great hall at the new Sorbonne is a notable endeavour to provide an audience of some 3000 persons with an ample supply of pure unwarmed air. The inlets are so contrived that this cold air, even in winter, passes through the great hall without causing a draught. The heat comes by radiation from all the walls and from every seat or article of furniture which has been previously heated.² This will be a great revelation to many of the county councillors if they can find time in the midst of all the festivities to study so serious a matter. But as they are the authority which in London controls theatres and other places like the Sorbonne, where large concourses of people gather together, this is a problem which is intimately associated with their work and responsibilities.

Such are a few of the matters connected with the preservation of public health which should prove of special interest to the London County Councillors on the occasion of their forthcoming visit to Paris.

Unwelcome Visitors.

THERE are worries affecting every class of the community which produce feelings of irritation often wholly disproportionate to the exciting cause; the irritation is, indeed, greater because the exciting cause is so trivial. Amongst members of the medical profession one of the chief sources of discomfort is to be found in the unnecessary disturbance of routine produced by an unexpected and perhaps unwelcome visitor who appears upon a "matter of business." No consideration need here be given to the consulting-room sneak, the light-fingered individual whose plausible story is told to servants and is intended solely to enable him to be left alone for sufficient time to annex portable property. We are referring now solely to the visits of travellers for various enterprising firms or foreign municipalities, who break in on the working day of general and consulting practitioner alike with eager persistency. We are generally addressed by the consulting practitioner upon the subject, but, as a matter of fact, country practitioners, especially those in a good position, are pursued with equal zest. It appears to be hoped that having often small leisure for reading they may thankfully receive up-to-date information without much destructive criticism of the terms upon which such information is imparted. Those who work in poor districts in town or country are often spared, perhaps because they frequently dispense their own remedies and so are likely to use fewer proprietary wares, but the practitioner who prescribes for the use of the druggist and the consultant, medical and surgical alike, are pursued relentlessly.

The type of caller varies from the agent of a firm interested in the employment of a new patent food to the peripatetic

THE LANCET.

LONDON: SATURDAY, FEBRUARY 3, 1906.

Overlying.

OUR Manchester correspondent¹ recently called attention to the frequency with which the suffocation of children sleeping with their parents takes place at Manchester at "week-ends," and he mentioned that four inquests had been held by the city coroner upon infants thus overlain during the late Christmas season. In the case upon which he was commenting four persons had been sleeping in one bed and this had been the condition also in two instances which recently occurred at Lambeth and with regard to which Mr. TROUTBECK held inquests on the same day. In one of these latter instances it was alleged by way of excuse that the bed in which the children usually slept could not be occupied by them because the rain came in upon it and the statement was made that in three years' time the house was going to be pulled down. However this may have been there can be little doubt that in a great number of cases poverty and the inability to provide a separate crib are pleaded by the parents as an excuse for the dangerous position which the infant occupies in their bed, and further, that a drunken or semi-drunken condition of both or perhaps only of the mother is in fact the cause of the child's death. The parents' drunken negligence ought to make them criminally liable. The Manchester coroner expressed himself to this effect and in the case alluded to by our correspondent avowed his intention to commit for trial upon a charge of manslaughter any parents overlying their infants against whom evidence of their being under the influence of alcohol could be found. The nature of the occurrence, however, renders such evidence almost impossible to obtain. The parents may live among neighbours whose standard of duty and of decency is no higher than their own; they may have been seen by no one when they returned home from the public house or they may have consumed their liquor in the privacy of their own room. They may not, moreover, have attained to a pitch of intoxication which those about them would recognise as drunkenness and yet may have been sufficiently fuddled by drink to fall asleep and to remain asleep in complete indifference as to the baby's welfare. Therefore, whether there is drunkenness or not, it is almost incapable of proof and if the frequency of overlying is to be diminished it must be done in such a manner that all cases may be covered and the matter must be considered generally and apart from a particular phase of it.

Mention has been made of the alleged poverty of the parents or parent, and in connexion with this the observation is often made that any box, such as an old orange box, can be adapted for use as a cradle. It must be borne in

mind, however, that the actual bedstead is not all that is required to make a bed and that warmth is essential to the young child. His parents may be sleeping in a bed almost devoid of blankets and bedding and they would no doubt say that although a box alone might be obtainable, bedding would be beyond their means. They probably reflect also that warmth by making the baby comfortable keeps him quiet at the same time and that when in the bed he can be nursed with the least possible amount of trouble to his mother. On the other hand, it may be said that a decent and an intelligent woman, fond of her child and solicitous for his welfare, would never sleep with him in the bed which she occupies with his father, and that where the parents at the time of the child's death are so poor that they could not have assigned to him bed and bedding of some kind the question may be raised whether this poverty is not due to their own fault. In other words, if decently behaved, frugal, and industrious parents can put their children to sleep in conditions consistent with their health and safety, must we permit other parents to imperil human lives merely because by their improvident and self-indulgent habits they have put it out of their own power to do otherwise? Can we not provide for the punishment of these in order to prevent the sacrifice of life without dealing too hardly with cases of extreme poverty where this is the result of genuine misfortune?

The word punishment has been used because it appears to us that if this particular variety of preventable infant mortality is to be put an end to the method adopted must be penal. Gentler measures, such as education and advice, would affect but few instances, for they would only appeal to women of a respectable class who as a rule do not adopt the practice complained of. Education and advice would have little effect upon the drunkard and would entirely fail to touch those whose action is more or less deliberate and intentional. We must not forget in dealing with this matter that the death of an infant in many families is, perhaps tacitly, regarded as a blessing and that in many those who would not deliberately compass it look back upon it with no regret. Instances occur in which a mother in the course of her married life overlies not one but several infants, with the inconvenience to herself that she may have to submit to reproof at the hands of a coroner but with the certain result that she avoids the daily burden of bringing up a family. As to the manner in which the law should operate this is hardly for us to suggest. In order that all parents killing their children in the manner indicated might be sent for trial and convicted in a substantial number of cases of manslaughter by criminal negligence no legislative change would be necessary, but it would imply the introduction of a new practice in which juries might or might not be willing to acquiesce, even though judges were favourable towards it. On the other hand, the compulsory provision of a separate sleeping place for a child under a fixed age would be objected to by some as an interference with the liberty of the parent and as tending to expose the child to suffering from cold. It would also be difficult to enforce. A parallel nevertheless may be found in the comparatively recent obligation laid upon parents to provide their children with medical aid when

Innotations.

"He quid ululit."

PROPOSED UNION OF MEDICAL SOCIETIES.

AT a meeting of the representatives of the various societies held on Dec. 19th, 1905, an organising committee was appointed to draw up a definite and detailed scheme on the lines published in THE LANCET on July 29th, 1905, p. 310, after consultation and discussion with each society which has expressed its willingness to join under certain varying conditions. One of the first essentials is to show that the scheme is likely to be a financial success. A reply post-card has been posted by the honorary secretaries to over 5000 individuals asking for an immediate reply to certain questions as to the probability of their joining the new society as Fellows or members. We understand that a Fellow will be asked to pay £3 3s. per annum for the privilege of attending discussions at all sections, of the free use of the general library, and of receiving the proceedings and transactions of the society. A member of a section will be asked to pay £1 1s. per annum for the privilege of taking part in the proceedings of that section, of receiving its publications, and of using the general reading room. Such a member will be entitled to join other sections at a subscription of 10s. 6d. for each additional section and to join the general library at a subscription of £1 1s. Every member of a society taking part in the amalgamation who desires to become a Fellow of the new society or a member of the corresponding section will be entitled to do so without election. Individuals elected subsequently to the constitution of the new society will have to pay entrance fees. As far as can be seen at present only original members of a section and those who are subsequently elected members of it will have the power to vote on matters directly affecting the affairs of such a section.

THE GUILD OF THE BRAVE.

UNDER the above title we have received an article from Dr. Helen McMurphy of Toronto pointing out the extraordinary heroism exhibited by hospital patients as well as their keen sympathy in the plight of their fellow patients and, sometimes, in the labours of the medical men and nurses. Every visiting or resident medical officer must have noted this and Dr. McMurphy's words, addressed to an imaginary house surgeon, will have the force of truth. "Yesterday you lost a public ward patient," she writes, "and as you passed on your round from the bed of death to those whom death had spared a very sick man looked at you gently and, forgetting his own desperate plight, said to you softly, 'You are disappointed, doctor.' The sympathy of that brave man went far to make you go on with your work." Many house surgeons can remember instances where the sympathy of one patient with another has been of the most practical sort, and nothing delights an inmate of a hospital, as a rule, more than to be given some detail to attend to in the treatment of another inmate. We received from another correspondent this week an account of a recent occurrence in a large general hospital, and the episode has a similar bearing. Two men were working in a lift when it fell with them for a distance of about 50 feet. They were taken out and brought to the hospital. One died before he could be got up to the ward. The other, a shattered mass of humanity, was put to bed to see if anything could be done for him. On recovering consciousness he said to the house surgeon who was sitting by his bed, "How's my mate?" and five minutes later he had rejoined him. Perhaps the most signal proof of the

courage of the average inmate of a hospital is the quiet manner in which he accepts the verdict of the surgeons as to the necessity for an operation. He comes to the hospital perchance because he has had difficulty with his bowels or because he has noticed that his urine is dark coloured. Two days later he is told that a "serious operation must be performed." He is very likely the bread-winner, and he makes up his mind that as he cannot work in his present condition he will face death. So he just tells his wife and resigns himself into the hands of those who, he feels, know better than himself. Truly to conduct such as this we may apply the words of Milton:

"Nothing is here for tears, nothing to wail
Or knock the breast, no weakness, no contempt."

"Our patients," says Dr. McMurphy, "are our masters in courage," and, indeed, to work in a hospital is to receive many a lesson in contentment, in patience under suffering, and in courage in bearing up in the most adverse circumstances. Well may Dr. McMurphy talk of the Guild of the Brave.

THE VOLUNTEER MOVEMENT.

A PROPOSAL has been put forward by Dr. F. Churchill before the Tactical Society of Edinburgh for utilising the services of the young men toilers in our crowded cities, many of whom are living in lodgings under very insanitary conditions, by providing accommodation for them in barracks designed and conducted very much on a club principle, similar in all respects to the "Rowton Houses." These should be erected in suitable and healthy localities where young men could be housed and boarded while they were being instructed and systematically drilled and trained. This has an important bearing also on the housing of the urban labouring classes. Supposing a convenient site in the suburbs of large towns to be selected for the erection of such buildings and the capital provided as a financial investment by philanthropic effort the Government might be asked to increase the capitation grant by 6d. a day (£9 2s. per head per annum) with the view of providing lodging for, and turning out, 50,000 efficient volunteers. Dr. Churchill considers that if this were done his project might be carried out at a relatively small cost to the State. It is needless to add that the scheme, if favourably viewed by the War Office, would have to be worked out very carefully, especially as regards its practicability and financial details, before its adoption.

THERAPEUTIC FASTING.

UNDER the heading of Common Colds in our issue of Dec. 23rd, 1905, p. 1854, we commented on a somewhat heroic method of treating colds recommended in America by Dr. Charles E. Page. We have since found that by a coincidence the *American Medical Record* of the same date contained an article by Dr. Page on the Curative Treatment of Pneumonia. He has also written to us from Boston expressing the opinion that pneumonia is mainly due to the use of "excessive clothing," and he proposes to treat it by a combination of hydrotherapy and fasting. His method of hydrotherapy consists of local cooling, not chilling by means of ice-packs but persistent cooling by a cold compress applied over the entire chest in front, the compress to be wetted with cold water as often as it becomes hot until the walls of the engorged blood-vessels have been braced to the point of resuming their normal calibre. When this stage of the treatment has been reached it is considered that the patient is convalescent and out of danger provided that his therapeutic fast is not prematurely broken. With regard to food Dr. Page says that from the time of Hippocrates to our own day therapeutic fasting has been the sheet-anchor of every expert sick-room dietist in

foreign practitioner, generally the accredited emissary of his locality, who is anxious to spread the knowledge of the remedial virtues of the special continental spa which is honoured by his habitation; but in all cases the personal interest of the caller is always evident from the first. Many such persons are excluded by a well-trained domestic who has received instructions to make minute inquiries about the business of all who come without an appointment, but such instructions are often defeated by the visitor who meets them with the presentation of a professional card. Medical men are always assumed to be glad to welcome members of their own profession and this fact is accordingly exploited by those who feel that a personal interview may favour the cause which they have at heart. In charity it is reasonable to consider that all these callers are primarily actuated by a praiseworthy desire to be useful to those upon whose over-occupied time they levy a tax. Many are merely carrying out the instructions which they have received and their untrifling industry may be regarded as commendable, though their methods may not be fully appreciated. That these methods fail to give universal satisfaction may be due to some lack of tact or discretion, some loss of the sense of proportion which may raise a smile or a frown when the caller proceeds to lecture his victim, incidentally showing that his didactic efforts are based upon insufficient data. It is natural that these usually unwelcome visitors should call during consulting hours. If they are to succeed in gaining access to the medical man they can only hope to do so by coming when others are hoped for or even expected. They pay a surprise visit and are, for the most part, pachydermatous when informed that the surprise is not a pleasure. This again they cannot be blamed for. And having gained admission, do they gain anything else? As far as pharmaceutical remedies go, let it be granted that medical men are glad to know the virtues of a new remedy and to make use of it at the earliest opportunity—while, in the French aphorism, it still possesses curative powers: the question still remains as to the best method of conveying this knowledge. There can be no doubt that to disturb a man at his avocation and to deliver a discourse upon the subject when that same man is burning to be left alone is not likely to conduce to business. The travellers too often assume an air of omniscience. They talk glibly a jargon which they believe to be scientific and do so with a patronising manner which conveys the impression that they have not troubled to ascertain whether their victim has any special knowledge of the subject or any chance of utilising the materials which are dumped down in the consulting room. They appear not to have realised that the Medical Directory might suggest a different tone and that to lecture a man upon his own subject is an idle proceeding. The general practitioner is requested to try the article and to order large supplies, on the ground that the consulting practitioners are all deeply interested in the remedy. The consultant is solicited to record his experience and may be surprised to find subsequently his name, with a few remarks separated from their context, appended to the "literature" relating to the new remedy. We cannot believe that such procedures really lead to an increased sale of pharmaceutical products.

It is in general easy for the medical man to secure immunity from agents of insurance companies, of motor-cars, and of encyclopædias. The first named are usually too tactful to require harsh treatment; the others are generally speedily open to conviction of the futility of making an attempt to prolong an interview. They are all business men who recognise the danger of undue persistence. Some are even sufficiently considerate to send an advance letter and to take no further steps unless this is answered. This, however, is not the way with another class of unwelcome visitors, a class that is getting more and more frequent, and a class upon which it is undoubtedly hard for a medical man to shut his door. We refer to unemployed nurses, masseurs, *inasseuses*, and the managers of nursing and hygienic institutions of all sorts. The nurses who come in the hope of securing work; those who come to announce that they have opened a nursing home in the immediate neighbourhood and have ventured to secure an expensive staff and have gone to lavish outlay in adaptation of primarily unsuitable premises; those who have endeavoured to march with the spirit of the times and have fitted up elaborate apparatus for the use of light, heat, or electricity in therapeutics—all these in soliciting work from those to whom they are unknown are really wasting time on both sides, while demonstrating the sad need of employment which has only been realised after the period of training. But without a doubt the most difficult caller with whom the medical man has to deal is the foreign practitioner, and for obvious reasons his visits are usually made to the consultants of London. He is anxious to show his accurate knowledge of the English tongue and this knowledge is not always as perfect as he fondly thinks. He advocates the special baths, waters, or sanatoriums of his district; or, on the contrary, while conceding that open-air treatment is good for pulmonary tuberculosis, he argues at length on the evils of massing together so many sick people and advocates treatment in small private houses in his locality. With such views he is not, of course, connected with the sanatoriums the advertisements of which have made the locality known, but he is ready to profit by their notoriety. He is always polite and deferential, even while keeping the main object in view, and he deprecates any selfish motive in calling, while indicating how much the municipality or neighbourhood whence he hails has done for the sick sojourner. He is difficult because his host frequently has no means of gauging his professional status; his name is unfamiliar and yet he may be a man of light and leading in his own country and above all he is a medical man and must receive the cordiality due to a *confrère*. The unwelcome visitors of the medical man are large in number and various in sort. Whether what they effect bears any proportion to the strenuousness of their efforts or the irritation which they sometimes cause is doubtful.

MORETONHAMPTSTEAD HOSPITAL.—The annual meeting of the subscribers to Moretonhamptstead Hospital, Devon, was held on Jan. 23rd, the Hon. W. F. D. Smith, M.P., presiding. The medical report stated that 67 in-patients were treated, being an increase compared with the previous year. The financial statement showed that a favourable balance of £35 remained.

are, in the main, poisonous substances, and although the effect of very small doses may be inappreciable yet the presence of a poison in beverages in any quantity at all is highly objectionable. There is convincing evidence to show that saponin is prejudicial to health and therefore its use for the purpose of causing a beverage to foam is forbidden in the provisions of the Sale of Food and Drugs Acts. Saponin is prepared from the poisonous corn-cockle which is quite a common plant in our fields and often a source of considerable trouble to wheat farmers. Even if saponin were not poisonous the practice of making things not what they seem is fraud, and nothing but fraud, and even if perfectly innocuous substances are used for the same purpose the intention is obviously again to deceive and to produce a wretched imitation of the genuine article.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE following are the arrangements for the annual course of lectures to be delivered at the College. The lecture hour is 5 P.M. The Hunterian lectures will be delivered by Dr. O. G. Seligmann, F.Z.S., on the Physical Anthropology and Ethnology of British New Guinea, on Feb. 12th, 14th, and 16th; by Mr. H. J. Paterson on Gastric Surgery, on Feb. 19th, 21st, and 23rd; by Mr. Arthur H. Ocheale on Some Points in the Surgical Anatomy of the Temporal Bone from Birth to Adult Life, on Feb. 26th and 28th and March 2nd; and by Mr. J. Warrington Haward on Phlebitis and Thrombosis, on March 5th, 7th, and 9th. The Erasmus Wilson lectures will be delivered by Mr. James Sherren on the Distribution and Recovery of Peripheral Nerves Studied from Instances of Division in Man, on March 12th, 14th, and 16th. The Arris and Gale lectures will be delivered by Mr. J. H. Watson on the Viscosity of the Blood, on March 19th and 21st; and by Mr. Sydney W. Carl on the Arterial Pulse, its Physiology and Pathology, on March 23rd.

CONFLUENT VARICELLA WITH SECONDARY FEVER.

VARICELLA is generally an exceedingly mild disease but the rule is occasionally broken by the occurrence of serious complications, such as nephritis or gangrene. In the *British Journal of Children's Diseases* for January Dr. J. D. Rolleston has reported the following very rare case. A boy, aged five years, was admitted into hospital on Oct. 8th, 1903, with a typical attack of scarlet fever. General desquamation followed and the temperature subsided by lysis to subnormal on the 18th and remained so until the 26th, when it rose to 99° in the evening. On the next morning there were numerous papules and vesicles characteristic of varicella. At 10 P.M. the lesions numbered 160. At 11.30 A.M. next day the vesicles alone numbered 254. On the 29th they numbered 794. On the lower part of the back the eruption was confluent and on the limbs it was semi-confluent. Several of the lesions were multilocular and some showed umbilication. Most of the vesicles on the trunk ruptured, leaving a bleeding surface. The albumin in the urine, which had appeared a few days before the onset of the varicella, increased from a trace to a cloud. On the 30th the vesicles numbered 2185 and their distribution resembled that of confluent small-pox. There were oedema of the face and swelling of the fingers which increased this resemblance. The vesicles were distributed as follows: trunk, 574; genitals, 30; thighs, 511; legs, 197; feet, 185; arms, 394; hands, 147; neck, 93; face, 50; and scalp, 4. There were several lesions on the hard palate. Haemorrhage took place into a few of the vesicles on the left forearm, the right knee, and the left ankle. On the 31st desiccation and incrustation were commencing. Many of the vesicles had become pustules, especially on the back. On Nov. 2nd the temperature fell by crisis and for about a week it

remained normal. Desiccation was not complete until the 10th, when many of the scabs on the trunk had separated. Their copious exfoliation and the associated factor were additional points of resemblance to small-pox. From Nov. 9th to 19th there was pyrexia due to suppuration beneath the scabs, which on separation left punched-out ulcers. By Dec. 4th all the scabs had separated and the child was discharged in good health on the 10th. The skin presented numerous scars showing various degrees of pigmentation. Very few cases of confluent varicella have been recorded. The absence of prodromal symptoms, the appearance of fully developed vesicles on the first day, the successive crops, and the shape of the lesions proved that the disease was varicella. The vesicular hæmorrhages entitled the case also to be termed hæmorrhagic varicella. Secondary fever in varicella has been described particularly by French writers.

THE MODE OF PRODUCTION OF SILK-WORM GUT.

AN interesting account of the history and mode of production of silkworm gut has been published by M. J. Triollet in the *Bulletin des Sciences Pharmacologiques* (1905, No. 5). It is obtained from the silk-producing glands of *Bombyx mori* at the time when the larva commences to spin. It has been known from very early times but was used for fishing purposes only until 1865, when Dr. Passavant of Frankfort-on-Main employed it in surgery. His example was later followed in this country by Mr. T. Bryant and Dr. Granville Bantock. Mr. Bryant, in the edition of his "Surgery" published in 1874, mentioned his experiences in the use of this ligature and recommended it for "quill sutures." Dr. Bantock employed the gut at first as a ligature for arteries and then as a suture. Silkworm gut is tenacious, flexible, and easy to tie in a surgeon's knot, and does not cut the tissues as is the case with metallic threads. Owing to its smooth surface it can readily be sterilised and removed from the patient without causing undue pain. It is rarely employed, however, as a buried ligature, being almost exclusively used as a suture owing to the impossibility of making with it so tight a knot as with silk or catgut. Although Italy produces large quantities of silkworm gut for fishing the surgical thread comes chiefly from the province of Murcia in Spain. The manufacturers supply the peasants with boxes containing an ounce of the eggs, sufficient to produce about 40,000 silkworms. These are hatched during April and May when the mulberry leaves begin to appear. The incubation occupies seven days at a temperature of from 22° to 30° C. The silkworms are microscopical at first and attain their full size in 24 days, moulting four times in succession. The longest and most vigorous are then set apart and carefully watched. When they manifest signs of beginning to spin they are killed by plunging them in a large tub of water acidulated with vinegar or citric acid, in which they remain from 12 to 15 hours. The dead silkworms are then taken one by one by women, who make a longitudinal incision along the back and carefully withdraw the intestine, stomach, œsophagus, and probably the greater part of the muscular and vascular tissue. They then isolate the two silk-producing glands and wash them with hot water. The glands are then manipulated by women specially skilled in the work who hold each gland by its ends and draw it out so as to produce one thread which is placed on a polished marble or granite table. In contact with air the thread rapidly dries and acquires a more or less blood-red yellow colour. This crude silkworm gut is then sold to the manufacturer and further treated. It is first boiled in alkaline water to remove fat and blood and is then dried in the sun, being protected from dust. It is next polished by means of slightly oiled pumice stone with an apparatus the secret of

all acute diseases. He never allows the ingestion of a morsel of any sort of food except water, or perhaps a little orangeade or lemonade, until the patient is practically convalescent. To milk he decidedly objects. Adults should have from two to four ounces of water at intervals varying from half an hour to two hours according to the amount and appearance of the urine. The water is given moderately hot and always with a placebo in some of the portions. Among his patients therapeutic fasts of five, eight, and ten days are not uncommon.

CANARDS AND CONSEQUENCES.

Mr. O. A. Ballance has recently had occasion to address a letter to the editor of the *Daily Mail* calling attention to the inconvenience that had been caused him by the insertion in that paper of a false statement that he had performed an operation upon the German Emperor. The editor of the *Daily Mail* inserted a correction without any apology for the mistake, giving Mr. Ballance's initials wrongly. We consider that Mr. Ballance has received scant courtesy from the *Daily Mail*. We saw the false paragraph, which we are informed was widely quoted, and we sympathise with Mr. Ballance in the disagreeable situation produced by its complete and reckless inaccuracy. In some of the versions of the story imagination went so far as to induce the writers to lay stress upon the great jealousy shown by German medical men towards English practitioners—an untrue special incident being used for the foundation of an untrue general conclusion. The most generous kindness is always shown to English medical men in Germany and in times when racial feeling is being used in many directions for political purposes such misrepresentations are particularly unfortunate.

DISSECTING ANEURYSM INVOLVING THE WHOLE AORTA.

DISSECTING aneurysm of the aorta is generally considered to be necessarily fatal. At the meeting of the Société Médicale des Hôpitaux of Paris on Dec. 29th, 1905, M. Maurice Letulle reported the following remarkable case which demonstrated that this condition may be compatible with life. A woman, aged 45 years, was admitted into hospital on August 5th, 1904. While in good health she was seized with breathlessness and a permanent feeling of constriction of the chest. She was taken to hospital in a state of grave dyspnoea. The precordial pain was not intolerable and did not suggest angina pectoris. The dyspnoea, though well marked, was not accompanied by polypnoea or cough. The face was pale and had an expression of pain. The apex beat was strong and situated in the sixth intercostal space, about 12 centimetres from the middle line, denoting hypertrophy of the left ventricle. A thrill was felt at the base of the heart and in the great vessels arising from the aortic arch. The aortic arch was enlarged and pulsated energetically in the suprasternal notch. Percussion showed that its right border was three centimetres from the right border of the sternum. There were a double aortic murmur, Corrigan's pulse, and capillary pulsation in the nails. The urine was increased in quantity and contained a little albumin. The evident dilatation of the aortic arch and its branches led to the diagnosis of chronic aortitis complicated by valvular insufficiency. The patient's age suggested that the condition was due to syphilis. She had been pregnant seven times. The two eldest children were living and in good health. The next four had died at an early age and the last pregnancy terminated in abortion at the third month. Under rest, a milk diet, blood-letting, and theobromine the patient improved. After a fortnight slight hæmoptysis occurred and the dyspnoea and precordial pain returned. The diagnosis of aneurysm

was then entertained. Five days later the hæmoptysis recurred. In the meantime paralysis of the inferior part of the right facial nerve appeared. Towards the end of August there were cardiac irregularity, dyspnoea, oliguria, and increasing weakness, and the patient constantly complained of neuralgic pains in the flanks. Death occurred on Oct. 26th. The necropsy showed considerable hypertrophy of the heart. All the valves were normal. The aortic arch was much dilated but showed no sign of aneurysm externally. The surrounding cellular tissue was thickened and sclerotic (chronic peri-aortitis). Contrary to expectation, the aortic valves were normal and competent. An extraordinary condition of the aorta was found. A dissecting aneurysm extended along its whole length and also along the innominate artery to its bifurcation. The aneurysm originated in an orifice, of about the size of a 50-centime piece, situated three millimetres above the aortic valves. At the bifurcation of the abdominal aorta it terminated in another orifice, a transverse slit five or six millimetres long. Thus during life the circulation of the blood took place through the aneurysm. This "accessory aorta" was about 35 centimetres long, its calibre, except at its origin and termination, was equal to that of the thumb, its lining was smooth, and its cavity was empty, not containing even a trace of clot. Microscopic examination showed typical rupture of the elastic coats of the aorta into which the blood had percolated following certain pre-existing planes of cleavage. The irritation caused by the forcing of the blood into this "interstitial wound" had led to the formation of a new coat of connective tissue, extremely thick. Thus the resistance and permeability of the new channel were secured. M. Letulle thought that the exit furnished to the blood at the termination of the aorta was a "spontaneous cure," as the condition established was compatible with life. The other lesions found confirmed the hypothesis of syphilis. The spleen contained a large infarct, the result of old arteritis. The kidneys were cirrhotic and showed end-arteritis. Similar changes were found in the vessels of the brain which were profoundly atheromatous.

FRAUDULENT FOAM.

FOAM is an undoubtedly attractive feature of many beverages which finds, perhaps, no better illustration than in the case of beer. Generally speaking the formation of foam on the top of beer is an indication that the beer is brisk as opposed to its being flat and stale, and since briskness is a wholesome quality of beer the appearance of a "head" upon its surface may be taken to be a sign that the beer is both palatable and suitable for drinking purposes. It is customary when pouring out beer from the jug to the glass to encourage the formation of foam by elevating the jug during the process so that the beer is gently splashed into the glass. If, then, foam is an indication of sound quality in genuine beer it seems to us to be a serious deception to manipulate a flat and possibly unsound beer with a "foaming mixture." The presence of a slight excess of carbonic acid gas in beer which gives to it a mild effervescent character is of distinct importance as a dietetic factor. Without this effervescence beer is prone to be indigestible and a beer-drinker instinctively avoids this beverage when it is "flat." The addition of a "foaming" mixture to beer therefore is calculated to destroy a useful and valuable means of discrimination and the consumer is thus not only deceived but his health may also be prejudiced by artificial foam. One, at any rate, of the substances employed to give a foam to aerated waters, and we have little doubt to beer as well, is saponin, very small quantities of which when added to water impart to it a frothy character. Now saponin is a glucoside, and glucosides

appliances in the production of which British manufacturers have held the first place would serve as useful object lessons, particularly as in Italy there is a growing market for these health-protecting products. This will be the first international exhibition of hygiene ever held in Italy and it should prove an excellent opportunity for showing how hospitals, sanatoriums, factories, workshops, private dwellings, and public buildings can be equipped with appliances for draining, warming, or ventilating such places in a satisfactory manner. The exhibition will be open from April to November this year and already more than a hundred national and international congresses are announced as about to meet at Milan during this period; one of these congresses will be devoted to the question of tuberculosis.

UNIVERSITY COLLEGE, LONDON.

A COURSE of eight lectures on Physiological Optics is being given in the physiological department of University College by Mr. J. Herbert Parsons on Fridays, at 5 P.M., the first lecture having been delivered on Friday, Jan. 26th. The syllabus is as follows. Lecture I.: Elementary optics—reflection, mirrors, refraction, prisms, and lenses. Lecture II.: The eye as an optical instrument—the homocentric system and the dioptric system of the eye. Lecture III.: Ophthalmometry. Lecture IV.: Ametropia—myopia, hypermetropia, astigmatism, and aphakia. Lecture V.: Ophthalmoscopy and retinoscopy. Lecture VI.: Visual perceptions—light sense, colour sense, and form sense. Lecture VII.: Accommodation and binocular vision. Lecture VIII.: Muscle balance and strabismus. The lectures are open to all students in London medical schools and also to qualified medical men on presentation of their cards. Professor E. A. Minchin will commence on Monday, Feb. 5th, a course of lectures on Parasitic Protozoa. Professor Minchin has recently returned from Uganda, where he has been engaged, as one of the special commissioners of the Tropical Diseases Society of the Royal Society, in research on the life-history of the trypanosome of sleeping sickness.

MEDICAL PRACTITIONERS AND THE NOTIFICATION OF INFECTIOUS DISEASES.

AN action recently brought against Dr. Louis Stamm, practising at Streatham, for negligence illustrates the extreme hardship imposed upon medical men by the law which lays them open to prosecution if they delay in notifying, or fail to notify, cases of dangerous infectious disease, while it affords them no protection against patients who consider themselves aggrieved by the notification should the diagnosis not be confirmed at the isolation hospital. In the case of Dr. Stamm a female patient, who had eaten shell-fish at Margate, became unwell, and after he had attended her for ten days he notified her case as one of typhoid fever. She was detained at the South-Western Fever Hospital for 17 days and there at some period subsequent to her admission the opinion was arrived at that her condition was due to influenza and not to typhoid fever, of which she became aware before, or at the time of, her discharge, with the result that she brought an action against Dr. Stamm founded upon his alleged mistake. There was no evidence whatever that he had been negligent and the medical officers of the hospital called on behalf of the plaintiff naturally and properly expressed their opinion that the defendant's conduct in notifying the case as one of typhoid fever had been perfectly correct. Dr. F. F. Gaiger, the medical superintendent of the hospital, who had been absent and had not himself made the diagnosis of influenza, was a witness and said that, having heard the story of the shell-fish and of the symptoms which the plaintiff was stated to have exhibited, he considered Dr. Stamm to have acted rightly in notifying that she

was suffering from typhoid fever. It was, in fact, a doubtful case and quite possibly was one of typhoid fever after all. The damage suffered by the plaintiff was apparently described as nervous shock due to her detention in the hospital and injury to her property occasioned by the disinfection of her flat. In these circumstances it is not surprising that the county court judge, the Hon. Arthur Russell, stopped the case without the defendant being called upon to make good his defence, and he is to be congratulated upon having done so firmly and decisively in such terms as left no doubt as to his view of the plaintiff's conduct. He also marked his sense of this by ordering the costs to be paid on what is known as the Q Scale, so that so far as possible the defendant will be indemnified for his necessary expenditure in resisting the claim against him. Perhaps Dr. Stamm would have preferred the opportunity of justifying his diagnosis in the witness-box but, be this as it may, the real lesson of the case lies in the fact that he had to undergo all the anxiety and expense of preparing his defence, however shadowy or non-existent the case of the other side might be. It is submitted to the good sense of the community that in its own interests and in those of justice actions such as this should not be permitted and that the medical man should be absolutely protected until a strong *prima facie* case can be made out against him, pointing not to erroneous diagnosis but to negligent and unskilful conduct resulting in a mistake which the exercise of ordinary professional skill and care would have prevented.

FEEBLE-MINDEDNESS IN CHILDREN.

THE growing literature upon the subject of the feeble-minded is indicative of the increasing interest which is being taken in this matter by medical men and educationists. There is abundant scope for the collection of scientific data in respect to the history and diagnosis of cases of feeble-mindedness in children upon which to found a rational system of education and care. To this subject Dr. C. Paget Lapage makes a contribution in the *Medical Chronicle*, 1905, based upon the examination of 253 feeble-minded children of Manchester who were pupils or would-be pupils of special schools, inmates of the home of the Lancashire and Cheshire Society for the Permanent Care of the Feeble-minded, or patients at the Children's Hospital, Manchester. The following were the etiological factors most commonly noted in these cases: a history of non-epileptic convulsions or one of epileptiform convulsions in the child; a family history of tuberculosis, of feeble-mindedness, of insanity, or of epilepsy; a parental history of alcoholism; and a maternal history of some abnormality during pregnancy. The various factors were usually found in combination. In regard to physical anomalies in the feeble-minded child Dr. Lapage found that out of 200 children examined 181, or 90.5 per cent., exhibited various "stigmata of degeneration." These are stated to occur much more frequently in the feeble-minded than in ordinary children and usually in combination, whereas in the ordinary school child single defects are more common. The question of the frequency of occurrence of such stigmata in the insane and mentally defective, as compared with normal individuals, and of the relative significance of the various stigmata is in need of elucidation. There is here a wide field for inquiry. In the cases recorded the head appears to have been examined more especially and attention is drawn to the frequency of occurrence of the following conditions: smallness of the maximum circumference, asymmetry, deficiency of the posterior part of the skull as compared with the anterior, defects of the external ear, and defects of speech and of facial expression. "Fetural" defects are stated to be hard to classify or to describe but are regarded

which is jealously guarded. The gut is then bleached with sulphurous acid and rubbed vigorously with chamois leather to remove dust and sulphur. The threads are finally sorted according to their thickness into five grades, varying from a tenth to half a millimetre in thickness. These five grades are known respectively as "very fine," "fine," "medium," "thick," and "extra thick." The two extreme sizes are rarely used. The fine threads should resist a mean pull of 2.5 kilogrammes, the medium threads 4 kilogrammes, and the thick threads 6 kilogrammes. A length of from 30 to 32 centimetres is suitable for surgical use. The gut is coloured by soaking for an hour or two in a solution of fuchsine or methylene blue and subsequently by washing thoroughly to remove excess of dye. In order to render it supple it is immersed for about six weeks in an antiseptic solution, usually a solution of phenol containing a little glycerine. Finally, the gut is sterilised in closed flasks containing an antiseptic solution in an autoclave at a temperature of 120° C. for half an hour. Silkworm gut so prepared varies much in quality, according to the thoroughness of the treatment to which it has been subjected. It loses its firmness on keeping. The annual production of silkworm gut in Spain is about 150,000,000 threads, the preparation of which provides employment for from 4000 to 5000 persons; the total value amounts to from 2,000,000 to 3,000,000 francs.

MEDITERRANEAN FEVER IN SOUTH AFRICA.

WE have received a reprint of a paper by Lieutenant-Colonel O. Birt, R.A.M.C.,¹ in which he concludes that Mediterranean fever is now endemic in certain parts of the Orange River Colony and that its further spread is likely to occur. Attention was drawn to the matter by some observations of Dr. P. D. Strachan² of Philippolis, Orange River Colony, on 72 cases of prolonged pyrexia which came under his care during a period of 18 months. The clinical features of the cases suggested to him the diagnosis of Mediterranean fever and in order to confirm this view he sent blood from 34 of his cases to the Government laboratories in Cape Town and Grahamstown. Of these, 25 gave an agglutination reaction with cultures of the micrococcus *Melitensis* in dilutions varying from 1 in 10 to 1 in 50. These results were the more remarkable since, apart from imported cases of Mediterranean fever, none of the cases of prolonged fever in the military hospitals at Harrismith, Bloemfontein, and Pretoria have suggested that disease, and in all the cases in which agglutination tests have been made with the micrococcus *Melitensis*, the results have been negative where trustworthy cultures have been used. It is well known that cultures which have been isolated for some time give results which cannot be relied on, since they become much too sensitive to the agglutinins present in normal blood. On the other hand, Colonel Birt and Captain G. Lamb³ have shown that with recently isolated cultures a complete reaction at a dilution of 1 in 10 or over implied Mediterranean fever past or present, and further, that this agglutinating power persists for months, or even years, after the disease has subsided; in one of these cases they obtained the reaction seven years after the attack. In order to subject Dr. Strachan's cases to a more stringent test Colonel Birt obtained samples of blood from a number of them and tested them with progressive dilutions of recent cultures and in every case he obtained a positive reaction, in some of them with dilutions of 1 in 1000. He therefore concludes that all these cases were actually Mediterranean fever. Dr. Strachan's partner, Dr. D. M. Macrae, has informed

Colonel Birt that he has seen similar cases in Fauresmith and Koffyfontein, and Springfontein and Bethulie have also presented cases of the disease. Dr. Strachan is of opinion that infection has been spread by goat's milk which is largely used in these districts. The subject is one which requires further investigation, since if this disease proves to be endemic in these districts it will be necessary to take active measures to prevent its spread. The actual demonstration of the organism in the blood of these cases has apparently not yet been made and Colonel Birt very rightly suggests that a search for it should be undertaken in doubtful cases of fever in the district.

WHAT IS WHISKY?

THE proceedings at the North London police court last Monday furnished very little evidence that could be said to be of particular interest or to possess any fresh feature. Sir James Dewar was recalled and gave some figures relating to the effect of age on whisky. He said that experiments showed that the longer a whisky was kept in wood the greater the increase in the impurities. (Readers of THE LANCET may remember that this fact has been pointed out in our columns as the result of a number of analyses made in THE LANCET laboratory.) In cross-examination Sir James Dewar admitted that for drinking purposes whisky was better for being older. Mr. William Sanderson, representing the North British Distillery Company, Edinburgh, said that to their customers they described patent-still spirit as grain spirit and pot-still spirit as whisky only. Asked whether he would have any objection to stating on the bottle that whisky is pot-still or grain, as the case may be, the witness thought that it might be done but that it "would not always convey anything." The difficulty would be to exercise control over the publican who bought the whisky in bulk. This witness agreed with another distiller that the public knew very little as to how or from what materials whisky was made. The hearing was again adjourned.

HYGIENE AT THE MILAN INTERNATIONAL EXHIBITION.

THE International Exhibition by which it is intended to celebrate the opening of the Simplon Tunnel was first meant to illustrate the past history and the modern development of the means of transport. Even this restricted programme included several questions of great interest from the point of view of health. The most obvious of these is the warming and ventilation of railway carriages. Then there is the great problem of food-supply—that is, the transport of live cattle and the railway cold storage cars for fish, meat, vegetables, beer, and other alimentary substances; medical examination, quarantine, disinfection of passengers and cattle vans and wagons—all these and many other public health problems form part of the general question of transport and travelling. But the programme has been enlarged. The exhibition will be held at Milan. An area of 840,000 square metres is secured and about a quarter of this space will be built upon. Here visitors will find what promises to be an attractive fine art section. Then there are sections on decorative arts and a working hall for industrial arts. There will be sections for agriculture, fishery exhibits, meteorology, aeronautic exhibits, social reform organisations, public hygiene, and, finally, a special exhibition of all that relates to the multifarious endeavours made to reduce the prevalence of pulmonary tuberculosis. The Italian executive committee, we are informed, is especially anxious to give great prominence to all questions connected with tuberculosis and to secure international coöperation in bringing forward all that bears upon the subject. The sanitary

³ THE LANCET, Sept. 9th, 1899, p. 701.

Limits are 15 minutes for a discourse and five minutes for either a demonstration or a speech at a discussion. The reading of printed or written matter is only allowed by special permission of the president.

THE CLIMATE OF ST. MORITZ.

WE have received a pamphlet with the above title and written by Professor A. Nolda, one of the resident physicians at St. Moritz, with the collaboration of M. C. Bühler, director of the Swiss Meteorological Station, Montreux. It is pointed out that the particulars previously published regarding the climate of St. Moritz have been chiefly based on observations made at Sils-Maria and Bevers, there being no continuous meteorological records for recent years at St. Moritz, but both the places named, especially Bevers, have a climate different in important respects from that of St. Moritz. Some interesting details are afforded in respect to the atmospheric pressure at St. Moritz, the temperature of the air, the relative moisture, the rainfall, overclouding and insolation, the duration of sunshine, and the prevailing winds. The pamphlet ends with words which we hope will not be substantiated by those responsible for the management of internal affairs at St. Moritz: "In one point St. Moritz has, with sagacious foresight, itself restricted and narrowed its indications—*St. Moritz declines to become a sanatorium for consumptives and will therefore not receive any patients suffering from tuberculosis of the lungs.* We sincerely trust that this wise decision, so necessary for the further development of St. Moritz, will be strictly carried out!" (The italics are as they appeared in the pamphlet.) We are of opinion that a great mistake will be made if such proposals are actually brought into force. Not only will a valuable therapeutic measure be denied to sufferers from tuberculosis but we believe that the authorities responsible for the enactment will have cause to repent their action. The climatic conditions of St. Moritz are admirably suited for the treatment of tuberculosis and there is no trustworthy evidence that the assemblage of patients suffering from the disease in any way affects the health of the community if suitable arrangements are made for the disposal of the sputum.

THE MEETING OF THE BRITISH MEDICAL ASSOCIATION IN TORONTO.

OUR Canadian correspondent writes:—The medical profession in Toronto is working hard to secure a successful meeting for the British Medical Association in that city from August 21st to 25th. The various committees are doing all in their power to make everything run smoothly and Dr. Reeve, the President-elect, of the medical faculty of the University of Toronto, has the loyal support of his colleagues. The honorary local secretaries are Dr. F. N. G. Starr, Dr. D. J. Gibb-Wishart, and Professor J. J. McKenzie, and anyone who desires any special information should apply to them at the Medical Building, Queen's Park, Toronto. It has been announced that the address in medicine will be delivered by Sir James Barr and the address in surgery by Sir Victor Horsley. The scientific part of the meeting will be conducted in 12 sections. Those going to Toronto will be assured of an enjoyable visit and afterwards they may judge of Canadian hospitality. The city has several fine hotels and the accommodation will be first-class. There will be excursions to Niagara Falls, to Muskoka, and to the Rocky Mountains. The last are nearly 3000 miles away but Canadians think nothing of that. The climate is the equal of any in the world. Toronto itself is an exceptionally fine city; its weather is delightful and this season there has not so far been any snow. It has numerous fine public buildings, a beautiful harbour and island resort, as well as steamboat

connexion with all the prominent health resorts. Intending visitors may be recommended to see Halifax, the Annapolis and the Matapedia valleys in the Maritime provinces; Quebec city and Montreal and the noble St. Lawrence in the province of Quebec; Ottawa, the capital, with its Parliament buildings; the Thousand Islands, Toronto, and Niagara Falls in Ontario; Port Arthur, Winnipeg, and the great wheat belt of Manitoba; and the Rocky Mountains, Vancouver, and Victoria in British Columbia.

THE medical officer of health of Cape Colony reports that for the week ending Dec. 30th, 1905, the condition of the colony as regards plague was as follows. No case of plague in man or other animal was discovered anywhere throughout the colony except at Port Elizabeth, where 2 plague-infected mice were found. For the week ending Jan. 6th, 1906, the colony was also free from plague except for 1 plague-infected mouse at Port Elizabeth. As regards the Mauritius a telegram from the Governor received at the Colonial Office on Jan. 26th states that for the week ending Jan. 25th there were 1 case of plague and 1 death from the disease.

A COURSE of ten lectures on the Physical Chemistry of Colloids (with special reference to immunity) is being delivered at the London Hospital Medical College, Mile End, E., on Fridays at 4.30 P.M., by Dr. J. A. Crow (British Medical Association Research Scholar). Lecture III., which will be delivered to-day (Friday, Feb. 2nd), will deal with various properties of colloids, ultramicroscopic investigations, diffusion and filtration phenomena, and the influence of light, heat, and electricity. Any member of a London school of medicine may attend this course.

THE Lettsomian lectures for 1906 of the Medical Society of London, on Some Points in the Surgery of the Brain and its Membranes, will be delivered by Mr. Charles A. Ballance, on Feb. 5th and 19th and March 5th, at 9 P.M. Lecture I. will deal with Some Points in the Surgery of Meningitis, Lecture II. with Some Points in the Surgery of Brain Abscess, and Lecture III. with Some Points in the Surgery of Brain Tumour. The lectures will be illustrated by lantern slides.

AN International Congress of Laryngology and Rhinology is announced to be held at Vienna in 1908, the date, already selected, being from April 21st until the 25th (Easter week). The date is selected as it is the fiftieth anniversary of the establishment by Türk and Czermak of a course of systematic study of laryngology in Vienna.

THE first of a course of lectures on Food and Nutrition will be delivered at the Royal Institution, Albemarle-street, W., on Tuesday, Feb. 6th, at 5 P.M., by Professor William Stirling, Fullerian professor of physiology at the Institution.

BY the will of the late Mrs. Gant, the wife of a former president, a sum of £100 has been left to the Medical Society of London.

A FEW REMARKS UPON THE REPORTS OF THE MALTA FEVER COMMISSION.

BY G. MURRAY LEVICK, M.R.C.S. ENG., L.R.C.P. LOND.,
SURGEON, ROYAL NAVY.

THE Government Commission on Malta Fever working at Malta under the supervision of the Royal Society has issued three important reports which have been read with great interest by all who have studied the disease. There are, however, some points which require discussion in connexion with the theory, to which Surgeon E. H. Ross, R.N., and I

as constituting one of the most common and noticeable of the abnormalities exhibited by feeble-minded children, and their combined effect is thought to constitute one of the greatest aids to diagnosis. The inquiry further showed that the feeble-minded are smaller and more poorly developed physically than ordinary school children, the disparity increasing with age.

HONG-KONG COLLEGE OF MEDICINE FOR CHINESE.

THE Hong-Kong College of Medicine for Chinese was founded in 1887, largely through the efforts of Sir Patrick Manson, Mr. James Cantlie, the late Rev. Dr. Chalmers, and the late Dr. William Young, for the purpose of teaching medicine, surgery, and midwifery to Chinese and such others as might avail themselves of the instruction given. The College has its headquarters in the Alice Memorial Hospital and the affiliated Nethersole Hospital is also open to students for purposes of clinical study. Students before matriculation must pass a preliminary examination in English, Latin, or classical Chinese, geography, elementary mathematics, and one modern language. The course of study extends over five years and includes more subjects than were required in English schools 50 years ago; the examination papers are also quite up to the English standard of that day and moreover contain questions on such quite modern topics as the treatment of appendicitis, the microbial pathology of various diseases, the examination of blood-stains, sphygmography, the theory of chemical valency, and the respective significance of free and albuminoid ammonia in drinking-water. Candidates on passing receive the diploma of Licentiate in Medicine and Surgery of the Hong-Kong College of Medicine for Chinese (L.M.S.H.). The teaching staff includes 16 lecturers, of whom 13 hold British qualifications. There were 35 students on the roll in December, 1905, and five diplomas were granted during the year then completed.

PATHOLOGICAL GLUTTONY.

THE literature of depraved appetites is considerable and is discussed at some length in Gould and Pyle's "Anomalies and Curiosities of Medicine." Morbid appetite most commonly manifests itself in the tendency to eat filthy or loathsome food, and this tendency again is allied to fetish worship. Many savages, for instance, consume their own excrements and assign ritual or religious reasons for this act. The human urine and faeces are by them regarded as containing the soul, and to devour them is to become repossessed of a sacred trust. That form of savage cannibalism which enjoins the eating of kinsmen and parents is based on the same grounds of reasoning. It is a question, however, whether cannibalistic and ordure-eating savages do not really derive their instincts from the lower animals. Dogs have notoriously depraved appetites. Some famous gluttons have certainly seemed to be casts-back to the lower carnivora. Such was "the Great Eater of Kent," affectionately eulogised by Taylor the Water-Poet. This Man of Kent was seen by Taylor to make a meal of a whole calf. He was admired in his day as a supreme instance of a jolly fellow, but his feats were such as to suggest the morbid and abnormal. Tarrare, a Frenchman, who died at Versailles, aged 26 years, during the latter half of the eighteenth century, was perhaps the most prodigious and revolting of those instances of what might be called pathological gluttony. He ate "a quarter of beef in 24 hours," and could quickly assimilate large serpents. Lorenze saw him devour a cat, the hairs of which he voided after an interval of half an hour, much as a bird of prey might do. This man was manifestly a reversion to type. Of his family, although less sensational in their cravings, are the earth-eaters, wood-eaters, chalk-peat, bog-, insect-, and perhaps even seaweed-eaters, while

the chewers and the whittlers may be said to belong to the same morbid category.

THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON.

AN important and valuable innovation is proposed to be introduced at the Hospital for Consumption and Diseases of the Chest, Brompton. A joint sub-committee of the committee of management and of the medical committee has been appointed to draw up a scheme whereby it is hoped the economic value of the hospital may be considerably increased. At the present time a lady almoner is appointed to attend in the out-patient department in order to render assistance in various ways to those patients who require it. It is now proposed to extend this department and so to make an endeavour to reach the patients in their own homes, to superintend the hygienic precautions which are necessary to prevent the spread of tuberculosis, and to make inquiries as to the state of health of those members of the patients' families who are dwelling in the same house. It is suggested that patients should be invited to bring other members of their families to the hospital so that they may be examined for evidences of tuberculosis. By pursuing such measures as these the work of the hospital will be rendered even more valuable than it is at present. As we have frequently pointed out, it is only by educating the public in the elementary laws of hygiene that any satisfactory stand can be made against the spread of tuberculosis. We trust that the endeavours which the Brompton Hospital hopes to make in this direction will be generously supported by the public, for considerable expense will be incurred if the proposals now being considered are to be carried out in a thoroughly satisfactory manner.

THE GERMAN SURGICAL CONGRESS.

THE thirty-fifth congress of the German Surgical Society will be held in Langenbeck House, Ziegelstrasse, Berlin, from April 4th to 7th. Members who by March 20th have paid their subscriptions for 1906 to Herr Melzer (Berlin N., Langenbeckhaus, Ziegelstrasse, 10/11) will receive their cards of membership by post. These cards may also be obtained at Herr Melzer's office in Langenbeck House on April 3rd and 4th but it is recommended that they should be procured in advance. The proceedings will commence with a general meeting for the transaction of miscellaneous business at 10 A.M. on April 4th and there will be a second general meeting in the afternoon of April 6th. Intimations of discommodities or demonstrations should be sent not later than March 3rd to Dr. W. Körte (Berlin W. 35, Potsdamerstrasse 39), together with a short synopsis and a precise statement whether a discourse or a demonstration is intended. Communications arriving at a later date can only be accepted if time permits. Patients arriving from abroad can be accommodated in the Royal Surgical University Clinic, Nos. 5-9, Ziegelstrasse. Preparations, apparatus, and instruments should be sent to Herr Melzer at Langenbeck House. An evening will be set apart for demonstrations of the Roentgen rays if sufficient material is forthcoming. The Congress dinner will take place on April 5th at the Savoy Hotel, Friedrichstrasse. Intending members should communicate with Dr. W. Körte, sending introductions from three members, and will be admitted at a committee meeting to be held on April 3rd. The following subjects have been selected for discussion at the Congress: (1) questions in military surgery, illustrated by the experience of the Russo-Japanese war; (2) the surgical treatment of ulcer of the stomach; (3) the further development of a high operation in cancer of the rectum; and (4) Bier's method of treating acute inflammation by vascular engorgement. The time

The smallest amount of blood from which the Commission succeeded in isolating the micrococcus is, according to its account, $\frac{1}{10}$ th of a cubic centimetre, or approximately four cubic millimetres of blood. I do not, however, agree that this excludes the possibility that the disease can be conveyed to a mosquito in a smaller quantity of blood. On the contrary, it seems obvious that the mosquito has only sucked up enough blood to convey one micrococcus to its stomach in order to transmit the disease and I would suggest that the scarcity of micrococci in the blood of patients (which is not after all very great) explains why the disease is not contracted by everyone who comes to Malta, as patients are nearly always bitten by hosts of mosquitoes. It is to be noticed that later in the report this escape of the many is mentioned as an argument against the mosquito theory of transmission but, as I have shown, it is really just as strong an argument in its favour. I think also that a mosquito may on occasion suck up more than four cubic millimetres, while, lastly, it is obvious that if a hundred mosquitoes bite a patient suffering from Mediterranean fever, which surely often happens, the total amount of blood abstracted by them is likely to be much more than the four cubic millimetres and may possibly amount to several hundreds of cubic millimetres, so that in this case not one but many of the insects may become infected.

I now come to Part II. of the report. On p. 43 we read: "Milk is not so closely connected with water in Malta as it is in most other countries, because the great majority of people get their milk-supply in their own vessels direct from the goat." I do not understand why vessels should not become contaminated by the water in the homes of the populace as much as vessels do in the dairies of other countries. Experience of the lower orders in Malta goes to show that they are not much more cleanly in their habits than the average goat and we read in the report of the Commission that in one house the occupants used the same bucket for washing the vegetables as they employed for carrying their excreta to the midden.

In Part III., at p. 37, we read that monkey No. 43 was repeatedly given hypodermic injections of broth growth from the breaths of Malta fever patients. The injections were frequently given from Oct. 27th to Dec. 4th. The blood of the animal was repeatedly tested for agglutination reaction with micrococcus *Melitensis* during the period of the experiment. I make the following extracts:—

On 7th of November doubtful tendency to agglutination. $\frac{1}{10}$ $\frac{1}{10}$; on 12th somewhat alling, on 22th slight agglutination reaction. $\frac{1}{10}$ $\frac{1}{10}$; on 5th of December tendency to agglutination in $\frac{1}{10}$ dilution, on 12th no agglutination reaction; on 15th dying, gave chloroform. P.M. Pneumonia and pericarditis. Inoculated slopes from all organs.

23rd December no M.M. recovered p.m., but a glucose fermenting + Gram staining coccus was obtained from spleen, liver, and kidneys, nothing from heart's blood and lungs.

In the remarks upon this experiment we read: "There is to be noticed in both these animal experiments the development of a low agglutination reaction and here, as in the skin experiments, I should attribute this to the ingestion of *M. Melitensis* toxins, as a certain amount of saliva trickled down the long entry tube and so into the broth." I would here point out, whilst admitting the possibility of the above conclusion being the right one, that it has been shown that agglutinins are not entirely specific in their action—i.e., that, in some cases at any rate, treatment with a particular organism may increase the agglutinating power as affecting other varieties of germs (Bouquet).

In the above experiments the broth injected was shown to contain germs other than the micrococcus *Melitensis* and the effect of injecting them was seen to be so marked at the post-mortem examination of monkey No. 43 that it is hardly surprising to read that in the serum of the animal the agglutinating power was increased sufficiently to act with a dilution of 1 in 20 upon the micrococcus *Melitensis*.

I might add, in conclusion, that Surgeon Ross and I have frequently suggested to members of the Commission that the true agent of infection is very probably the mosquito *Anopheles Zambesi*. Our experiments, observations, and arguments which lead to this conjecture are given in our paper in the *British Medical Journal* of April 1st, 1905, and the *Journal of the Royal Army Medical Corps* for August and September, 1905. It seems a pity that experiments have not been thoroughly undertaken to prove whether or not *Anopheles Zambesi* is the real agent of

THE WINES OF THE GIRONDE WITH SPECIAL REFERENCE TO CLARET.

THE statement which appeared in an annotation in THE LANCET¹ a little over a year ago that "Bordeaux wines or clarets were never cheaper, more abundant, and purer than they are in the present day" proves to be well founded in view of the results of a practical inquiry which we have recently undertaken. It is somewhat remarkable, therefore, that the belief still gains currency that the bulk of the claret sold at the present time in this country is too cheap to be good and that the genuine produce of the Médoc can only be obtained at relatively high prices. In giving an immediate answer and denial to this we may as well state at once that we have purchased wines in the open market, in London at all events, at wine merchants, stores, and grocers' shops at prices varying from 1s. to 3s. a bottle which have proved to be not only genuine but wines of excellent quality also. It is, indeed, highly probable that as a matter of fact the best value in regard to wines at the present time is to be obtained in clarets.

As we shall presently point out, the public, speaking generally, either has uncertain views about claret or, and this is worse, regards it as being deficient in that stimulating power which is only too freely found in strong fortified wines or spirits. The view is unfortunately too commonly held that the most trustworthy form of stimulant is whisky or some other spirit and that these contain alcohol in a pure and harmless form; therefore it is thought that in the choice of a stimulant it is safer to avoid a light wine the origin and genuineness of which are open to doubt. It is probable also that the use of light wine as a beverage has fallen into disrepute because it has happened occasionally that both the palate and the pocket of the public at some time or other have been trifled with by unscrupulous dealers; we are convinced, however, that this is only a fractional reason, although it may well be accountable for the practical absence of a demand for light red wines on the hotel table. Nowadays it is quite exceptional to find claret called for at hotels, for the simple reasons that, firstly, the price asked for it is exorbitant and, secondly, the wine supplied is frequently of a very inferior quality, if, indeed, it is not sour and undrinkable. In these circumstances it is not surprising that whisky and water (plain or aerated), regarded, as it generally is, as being above suspicion, has come to be the common accompaniment to a meal at the hotel. We believe that if hotel proprietors would undertake to provide their patrons with a sound Médoc wine at a reasonable price—say, 2s. or 3s. a bottle—they would find the step very widely appreciated and a profitable one. The objection generally urged, however, is that such a scheme would leave no margin of profit. This seems to us unlikely when we call to mind the fact that in almost every little inn in France a bottle of good sound wine can be obtained for 2 francs or so. It may not be a wine of great quality or delicacy but, generally speaking, it is at least a "clean," wholesome, and genuine vin ordinaire. The small margin of profit theory is, moreover, illogical, since a bottle of whisky for which 5s. or 6s. are charged and which is made to last for perhaps a week, would leave surely a smaller margin of profit than a bottle of claret ordered with each meal.

But there are other factors which have led the public taste in this matter to disregard delicate light wines in favour of more potent beverages. Good sound claret is the most

have been led by a process of exclusion, to the effect that the infection may possibly be conveyed by the mosquito *acartomyia Zammitii*. I wish particularly to examine some of the experiments of the Commission which tend to lead in another direction—namely, that infection may be acquired through the respiratory or digestive tract—but which appear to be not so conclusive as might be inferred from the reports.

I will commence at p. 46 in the first publication. Here, in Experiment I., we find a description of an attempt "to determine if the inhalation of dust infected with *micrococcus Melitensis* will give rise to Mediterranean fever in healthy monkeys." We are told that on July 10th, 1904, monkey No. 41 was placed in a cage and "infected dust blown around him." (This dust was mixed with living cultures of the *micrococcus Melitensis*.) 24 hours later infected dust was again blown round the monkey and when an hour had elapsed the animal was taken from the cage, which was then disinfected. The skin of the monkey, which must by then have been liberally sprinkled with living *micrococcus Melitensis*, was apparently not disinfected; at any rate, no mention is made of such precaution being taken. For a month or so the same procedure was continued daily. On Sept. 6th the monkey was found to be suffering from Malta fever and the result arrived at by the Commission was that "this experiment seems to show that inhalation or ingestion of infected dust will give rise to the disease." Now we know that these animals spend much of their time in scratching themselves and it therefore follows that during this experiment monkey No. 41 may have been repeatedly inoculating himself by scratching living *Micrococcus Melitensis* into irritated portions of his integument, which must have been in a very infectious condition, so that the result of this experiment may very probably have been merely an example of the contraction of the disease by inoculation. It is therefore quite possible that the conclusion arrived at by the Commission is not warrantable.

Again, under the heading "Experiment II.—to Determine if Injection of Dust Infected with *Micrococcus Melitensis* into the Nostrils and Throat will give rise to Mediterranean Fever in Healthy Monkeys," we read: "Monkey No. 47—July 9th—Injected dry dust containing *micrococcus Melitensis* into both nostrils." The injection was repeated on the 10th, 11th, 12th, 13th, and 14th. "29th.—Injected dried infected dust into back of throat; lips covered with cloth and tube passed through a wooden gag." This procedure was repeated daily until August 8th, on which day the monkey was found to have contracted Malta fever and we read: "Result.—From this and the last experiment it is evident [the italics are mine] that the inhalation and swallowing of infected dust will give rise to Malta fever in monkeys." Let us review this experiment. First of all let it be noted that for six consecutive days dust mixed with living *micrococcus Melitensis* was injected into the nostrils. The dust probably irritated the nasal mucous membrane, so that mucus containing living *micrococci* would run on to the lips, &c. Also the posterior nares must have been swarming with living *micrococci* and probably inflamed by the repeated dust injections. Both at this time and later, when from July 29th to August 8th daily injections into the back of the pharynx were carried on, I take it the mouth was also in a continually infectious state, so that the precautions adopted with the gag and cloth might have been futile because, as admitted in a note written on August 9th, there was "a very small abrasion" on the skin of the lower lip. I therefore suggest that the result of this experiment does not appear to justify the conclusion that "it is evident that the inhalation or swallowing of infected dust will give rise to Mediterranean fever in monkeys." It is well known that the disease is inoculable and I think that some undiscovered crack or abrasion of mucous membrane is almost sure to be infected when such enormous and unnatural quantities of infected material are used repeatedly over a considerable length of time.

Turning now to Experiment III., we find that monkey No. 39 was fed for 32 consecutive days upon pure cultures of *micrococcus Melitensis* mixed with boiled potatoes, the feeding having been commenced on July 10th and discontinued on August 10th, on which date the animal's blood was found to give a marked agglutination reaction for *micrococcus Melitensis*. Later the monkey was killed with chloroform and the organism was recovered from the spleen. After a description of the experiment and result we read: "Result.—

The absorption of *M. Melitensis* was extremely slow, but the monkey eventually suffered from an acute infection." I do not follow this argument. Had the monkey been fed *once* and contracted the disease 32 days afterwards, it could have been understood and have been admitted that the absorption was slow, or the incubation period possibly 32 days. But owing to the way the experiment was carried out it seems at least as likely that the monkey escaped infection until (say) August 2nd, giving an incubation period of about eight days only. This would be a different thing from "slow absorption" and I mention it as an important point in the investigation of the disease. Again, if the possibility which I have suggested be the right one it may be seen that the monkey might have swallowed pure cultures mixed with potatoes for about 24 consecutive days without becoming infected and this circumstance would then be a very strong argument against the theory of infection by the gastro-intestinal tract. The pitcher being taken so often to the well may have broken, as to speak, on the day when a lesion of the mucous membrane appeared.

In a description of Experiment V. we read: "13th August, 1904. This monkey is in a box next to monkey 39 and I noticed, about a week ago, that he ate some of the infected potatoes provided for No. 39. Examined blood serum; reacts instantaneously. This experiment is probably an instance of direct absorption of *M. Melitensis* through a crack or abrasion of the mucous membrane of the mouth; the period of incubation and the wave of fever correspond exactly with monkey No. 72 which was infected with *M. M.* through a crack in the mucous membrane over the incisor tooth." If infection was contracted through a crack in this case, why not in the other cases?

During September, 1904, several of the monkeys kept for experimental purposes contracted the disease without apparent cause. Major W. H. Horrocks, R.A.M.C., says in his remarks that this is probably due to infection conveyed from neighbouring monkeys. As diseased and healthy monkeys were kept on the same terrace close to one another, and mosquitoes also had free access to them all, this certainly seems to be very likely. Continuing his remarks, it is said: "On the other side of monkey No. 46 is monkey No. 47 infected by dust blown into the throat—evidently this monkey has become infected, either by personal contact, by urine, or by means of *stegomyia*. But why *stegomyia* in particular? Other species of mosquitoes had access to the animals.

Many other feeding experiments of the same kind were carried out, and it seems to me that the objections given above are applicable to them all. These are: (1) the monkeys were not isolated; (2) mosquitoes had access to them; and (3) it is impossible to say that the mucous membrane of the mouth and pharynx was free from lesions. With regard to Experiment VI., "to differentiate between absorption from the mouth and throat, and absorption from the stomach and intestines." In this experiment infected milk was passed into the monkey's stomach by means of an indiarubber tube. After the milk was introduced to the stomach the tube was presumably hauled up again, so that the end of it, being smeared with milk and *micrococci*, must have almost certainly infected the oesophagus, pharynx, and mouth. I would suggest that the stomach should be infected by means of capsules containing the emulsion pushed down the oesophagus by means of a bougie (under chloroform if necessary). The capsules would dissolve in the stomach and the upper tract would not be infected.

From the "conclusions" set down at the end of Section 4 I quote the following: "Infection by means of urine secreted by cases of Mediterranean fever readily explains the cases of Mediterranean fever which appear to arise spontaneously in hospitals." I do not agree with this conclusion because fresh cases do not arise in Haslar Hospital, where old cases have been kept in the wards for many years. It is only in hospitals in the endemic area that cases arise "spontaneously." Surely this is a most important point.

In Section 5 a description is given of methods for cultivation of the *micrococcus Melitensis* from the blood of patients as carried out by Staff Surgeon R. T. Gilmour, R.N. At the end of this description we read the following remark by the editor: "It is evident from Staff Surgeon Gilmour's experiments that the *M. Melitensis* is present in the majority of cases examined. Their number is, however, so small that it seems extremely doubtful if the disease can be carried by biting insects."

MAP OF THE WINE-PRODUCING DISTRICTS OF THE GIRONDE.

Area approximately = 65 x 80 miles.
Area under cultivation about 400,000 acres.

delicate as it is the least intoxicating of wines. The exquisite flavour of the Médoc wines in particular is easily spoilt and modern habits of living and of feeding conspire to blunt the delicate sense of the palate. The smoking of a cigarette or cigar, for example, invariably spoils the flavour of a choice claret and quite destroys the chance of appreciating and enjoying the taste and bouquet of a delicate wine. Coffee and liqueurs and even heavy wines, on the other hand, appear to many as agreeable accompaniments to smoking, the flavours of these liquids not being readily spoiled. Even so, these habits, whether we condemn them or not, should have no effect with respect to the claret consumed during a meal. Few now reserve a glass of Lafite or Margaux or Latour for after-dinner drinking, the use of port, liqueurs, or coffee, or of all three, having replaced the delicate and more interesting Châteauneuf claret. It has been said that it is only the man of refined tastes who can appreciate to the full the refinements of a "classed" Médoc wine or who can differentiate between vinous vulgarity and delicacy, and this is a factor which tends to reduce the ranks of appreciative claret drinkers. Certainly claret is abandoned by many, it is to be feared, because, as *Mr. Punch* once put it, "you can't get no forrader on it." Continual spirit drinking undoubtedly interferes with the relish for the less potent but more "flavoury" wines. Simplicity of diet at the table, again, was more the rule when claret was in favour, whereas the present custom is to adopt a number of varied courses, comprising *hors d'œuvre*, piquant sauces, highly seasoned dishes, savouries, and so forth, which help to destroy the chances of appreciating the best characteristics of a really elegant and interesting wine. These are, at all events, some of the contributory causes of the decline in the consumption of light wines, and it is a question worth considering whether this decline, in view of the adoption of stronger wines or of ardent spirits, is not without an unfavourable influence on the health and *morale* of the people.

There are few social reformers who do not agree with the view that the less alcohol that a nation drinks the better. It surely follows that the less potent the alcoholic beverage is the better also, for in that case the physiological allowance of alcohol is less likely to be exceeded. The spirit-drinking habit as opposed to the indulgence in light natural wines is deplorable, especially when it is largely confined to potations between meals. It should be remembered that for all practical purposes, and certainly as compared with wine, whisky is pure alcohol and that therefore a mixture of whisky and water is a very different thing from wine, although the alcoholic strength of both may be the same. It may be remembered also that pure alcohol as such is never a natural product; it must be separated from the environment in which it is produced by means of the still. The physiological effect of ten ounces of whisky and water containing 10 per cent. of alcohol and ten ounces of, say, claret containing also 10 per cent. of alcohol is notoriously different. The former instantly produces a marked sense of stimulation and warmth in the stomach; the latter is exceedingly slow in producing a similar effect, if, indeed, it is produced at all, and yet the amount of alcohol in the two liquids is the same. The physiological effect of the alcohol in the wine is modified, no doubt, by the natural constituents of the wine, such as the acids, tannin, glycerine, extractives, and so forth. It would appear, therefore, that the alcohol in claret is not so readily diffusible as is the alcohol in a mixture of spirits and water. Sparkling wine, such as champagne, proves to be a readily diffusible stimulant, probably because the effervescence acts as a stimulant to the movements of the stomach. The physiological effect of alcohol in claret is in some way checked and claret is thus less rapidly stimulating than a mixture of spirits and water containing the same proportion of alcohol; in other words, the former is a gentle, while the latter is a rapid stimulant. "It is a profound mistake," writes Dujardin Beaumetz, "to regard wine as a mere mixture of alcohol and water; it is a complete living entity, of which all the

elements constitute an *ensemble* so complex and heterogeneous that we cannot modify one or another without producing profound changes in the composition of the wine itself." Possibly the slow rate with which alcohol in claret is absorbed as compared with that of spirits and water is due to a difference of osmotic pressure exercised by the dissolved constituents of the wine. It is well known, at all events, that pure distilled water (that is, water which contains no salts) will act as a protoplasmic poison. If tissues or cells are placed in distilled water the water rapidly passes into the cells owing to the difference of osmotic pressure. The cells swell and may burst and die. This process in the stomach may lead to catarrh of the organ, the surface layers of the gastric epithelium undergo considerable swelling, salts may pass out, and the cells die and be cast off. Gastric catarrh, as is well known, is an invariable symptom of the confirmed spirit-drinker and it is conceivable that the purity of the alcohol which he constantly imbibes is a contributory factor to this catarrh owing to the difference of osmotic pressure between the alcohol and water and the gastric cells. On the other hand, the difference between osmotic pressure when wine is consumed must be relatively small owing to the extractives, glycerine, acids, and other constituents dissolved in the wine, and the passage of wine, unless it is strong and highly fortified, into the cells must be relatively slower. The placing of a slice of lemon in spirit and water would, in view of the phenomenon just referred to, tend to reduce the difference of osmotic pressure in a similar way.

In this connexion it is interesting to observe that there is a very excellent institution the members of which call themselves, we believe, semi-teetotallers who pledge themselves not to drink alcoholic beverages between meals. Common sense heartily approves of this form of abstinence from alcoholic liquors and though there are very many other cogent physiological considerations which clearly teach that such a course must be conducive to health, further proof of the discretion of such abstinence is furnished by the osmotic effects just described which indulgence in spirits is calculated to bring about. A consideration of this fact also teaches a lesson in regard to the drinking of light wine as opposed to the drinking of spirits. It would be interesting if those scientific men who condemn root and branch the use of alcohol in any form would conduct an experimental inquiry on the lines indicated and determine whether it is correct to assume that the physiological effect of alcohol in the form of wine is the same as when pure alcohol is given. There can be little question that a light natural wine is infinitely less harmful physiologically as regards alcohol than are ardent spirits. No better evidence in support of this can be cited than the fact that in spirit-drinking countries crime and disease ascribable to alcohol are the rule, while in countries where light wines are even freely consumed the evils arising from drink are the exception and drunkenness is comparatively unknown. So strongly has the fact impressed itself on certain communities that steps have been taken to encourage the drinking of light wines by reducing the duty on them in the hope that the consumption of spirits would be discouraged. In Paris, for example, the "octroi" on wines brought into the city have been taken off with the view of encouraging the drinking of light natural wine and of diminishing the vicious results occurring from the consumption of ardent alcoholic liquors, such as spirit, absinthe, and so on. The moderate drinking of claret in particular has been credited with diminishing the tendency of preserving a sober standard and of leading to the abandonment of the daily libation of powerful spirituous liquors. On temperance grounds it is a pity, we think, that the duty on really light natural wines imported into this country cannot be reduced to an even lower rate than it was some years ago. Really light wine might with advantage, we suggest, come under a lower scale of duty than is at present charged, the same rate now being put upon wines of a higher alcoholic strength than claret. In wine-producing countries, again, light natural cheap wine is consumed in large quantities, amounting to as much as two pints a day without any observed ill effects on the health. Sociologically, therefore, the decline in the consumption of light wines in favour of stronger drink demands serious consideration.

At the outset we stated that Bordeaux wines or clarets were never cheaper, more abundant, and purer than they are at the present time. It is necessary to examine carefully and

The Graves district borders on the river Garonne and produces both red and white wines. Amongst the favourite red wines are those of Château Haut Brion, just west of, and quite close to, Bordeaux, which in fact is classed in the first division; Château Smith, Haut Lafitte, and Château Haut Bailly. The classification of the white wines of the Gironde relates to the wines of the Sauternes, the Grand first growth being that of the world-famous Château Yquem, while other wines enjoying distinction in the first class are those from La-Tour-Blanch, Peyraguey, Vigneau, and Rabaut in the Bommes district; Château Coutet, Climens at Barsac, Château Suduiraut at Preignac, Château Guiraud at Sauternes, and Château Rieussec at Fargues. In the second class are wines from Château Mirat (Barsac), Doisy (Barsac), Peyxotto (Bommes), D'Arche Filbot (Sauternes), Broustet-Nérac (Barsac), Caillon (Barsac), Souau (Barsac), Malle (Preignac), Romer (Preignac), and Lamothe (Sauternes). The chief town in the Sauternes district is Langon, which is beautifully situated on the banks of the Garonne. The most important wines produced in the Côtes are those in the district of St. Emilion. They are often called, on account of their full body and generous character, the *burgundies of the Gironde*. Amongst famous growths are Châteaux Ausone, Cheval Blanc, Bel-Air, and Pavie. Close by is Pomerol which also produces wines of estimable character. St. Emilion is a most interesting and picturesque town situated in a charming district of hills and vales, about five miles east of Libourne on the river Dordogne, the bridge

grapes should be pressed at all; so much of the juice escapes by the pressure of the fruit itself and during the process of separating the stalks that the semi-liquid mass containing whole fruit is transferred straight away into the vat without further attention. In the majority of cases, however, the grapes are carefully picked and pressed but the skins are always put into the juice in the great vats. We give an illustration in Fig. 4 of a typical *pressoir*. Fermentation steadily proceeds in these vats which are closed in order to keep the generated carbonic acid gas as much as possible in the vat and thus to protect the wine that is developing from the action of the air. The escape of gas is provided for by a small pipe dipping into a water seal. The bubbling noise of the gas passing through the water in an otherwise perfectly quiet *curier*, where there may be a dozen vats of immense capacity each contributing its volume, is a strange and impressive sound. The primary fermentation being concluded, after about ten days the young wine is drawn off (*décuvage*) and eventually transferred to scrupulously clean hogsheads (*barriques*). The hogsheads are placed in the cellar where the wine is jealously watched during its development and the only care that remains to be bestowed upon it is in the racking (drawing off the clear wine from the lees or residues) which is done as often as there is occasion, according, in fact, to the development of the wine. A comparatively quiet secondary fermentation succeeds the first but soon subsides until practically the whole of the grape sugar is exhausted. There is little doubt that careful

FIG. 1.

The gathering of the grapes.

over the river being part of the national road running from Bordeaux to Paris. All the districts just described were visited by our Commissioner during vintage time. And we may now pass to the methods of making the wine from the grapes as he saw them practised in these districts.

WINE MAKING IN THE GIRONDE.

There is surprisingly little to describe in regard to the method of making wines in the Gironde for the excellent reason that it is simplicity itself and we doubt whether any other wine than claret can claim to be left so entirely to purely natural processes. Indeed, claret makes itself without even the intervention of a press in some cases, for in the ordinary processes of picking, carting of the grapes, and separating the stalks some of the juice is liberated; fermentation rapidly sets in and the berries that happen to remain whole in the vat burst, their juice joining in the fermentation already established. The grape is black, with a diameter of about that of a threepenny piece, and in a healthy state is usually covered with a strong bloom. The colour of claret is entirely due to the skins and if these were omitted from the vat practically a white wine would result. All grape juices is white whether the grape is white or black. Vintage time in the Médoc affords a very interesting and picturesque sight. We reproduce some photographs illustrating in Fig. 1 the gathering of the grapes, in Fig. 2 the removal in carts drawn by oxen to the *curier* (Fig. 3) the place in which the grapes are pressed and the wine is stored in vats.

As already stated, in some cases it is not necessary that the

and well-timed racking is a very important factor in the production of a good wine and any neglect to carry out this simple operation may make all the difference between success and failure. With ordinary wines bottling may be commenced at the end of the second year, but as a rule fine and full-bodied wines are not bottled until the end of the third year or fourth year or even after a longer period.

Such, in brief, is the story of the making of claret from the juice of the grape and the entire process is extremely simple, being effected from beginning to end by what practically amounts to purely natural agencies. The grape juice ferments until fermentation ceases and in order to gain a clear and brilliant product the resulting wine is simply poured off from certain insoluble matters, as from time to time they subside and are thrown out by the alcohol produced. The degree of cleanness and brilliancy depends upon the care and regularity with which the racking is done. The word claret is probably derived from "*clair*," cleared or clarified (Latin "*clarus*," clear). It was but a step from the old French participle "*clairé*" to the adjectival noun "*clairé*" or, as we have it, Anglicised, "claret." The clearing process is often assisted by fining the wine with white of egg, which process adds nothing foreign to the ultimate wine but merely withdraws matters identical with those thrown out in the ordinary course of events in the natural deposit. There are, of course, certain minor details connected with the management of wine during its development but we have confined our account to the principal and essential steps in the simple operation. Suffice it to add that at no stage in the

minutely into this statement in order to determine whether it can be justified by first of all looking into the facts connected with the production of red and white wines in the districts of which Bordeaux is the centre in the south-west of France; and, secondly, by submitting to the test of the palate and of chemical analysis samples of wine which are known to be genuine because obtained personally at the place of production and comparing the results with wines bought in the open market. Finally, it will be of interest to discuss the composition of wine in relation to its dietetic uses. We are aware, of course, that the composition of Bordeaux wines has been determined again and again by numerous observers and a great number of more or less trustworthy analyses have been published; nevertheless, we venture to think that in the work of the practical and scientific inquiry recently undertaken by our Special Commissioner there are presented some new features in analysis which are of special interest in connexion with the dietetic value of wines. We may resolve our inquiry therefore into the following order of investigation—namely, an inspection of the processes concerned in the production of Bordeaux wines, the normal composition and characteristics of genuine wines obtained personally at their source, and the general composition and characteristics of wines sold in the market as claret; finally a section is devoted to some points in connexion with their dietetic application.

THE WINE-PRODUCING AREAS OF THE MÉDOC, GRAVES, SAUTERNES, AND ST. EMILION DISTRICTS (GIRONDE).

The reputation of the wines of the Gironde has been built upon the yield of an area represented in some 400,000 acres under cultivation, while the complete district is not more than 65 miles by 80 miles, or an area of 5200 square miles. The whole wine-producing area of which we speak is, in fact, rather less than the area of the county of Yorkshire in England and yet it has furnished the world's claret supply for years and years and no other country in the world can compete with it in producing wine of equal delicacy, fragrance, and elegance. From the year 1880 onwards the production has steadily increased, although the area under cultivation has remained much the same; improved methods of cultivation have in fact resulted in a greater yield of fruit and hence of wine. Of course, some years show a diminished yield owing to unfavourable meteorological conditions, frost or wet it may be or insect ravages. The yield in 1880 was 36,000,000 gallons and in 1900, the most prolific year, it was 128,000,000 gallons; in 1904 it was 99,000,000 gallons; and in the last vintage (1905) the production promises to be about 95,000,000 gallons. The division of the entire department into six districts is shown in the map (p. 321). The districts are as follows and are indicated in the map by various shadings: Médoc, Graves, Sauternes, Côtes, Palus, and Entre-deux-Mers. Strictly speaking, the only district bordering on the Gironde, if we except certain small low-lying districts chiefly on the east bank and known as the "Palus," is Médoc itself. The name Gironde is applied to the estuary of that river and nearly 50 miles from the mouth it divides into the Dordogne and the Garonne at a point just above Blaye. The Garonne then traverses the districts where the wines of the Graves (white and red) and Sauternes district (white only) are produced, while the Dordogne runs through the valley on which borders the famous St. Emilion district (red wine). All these districts were visited by our Commissioner during the full operations of the 1905 vintage. The wines produced in these districts are broadly spoken of as the wines of the Gironde and the red wines are all included under the name of "claret."

Bordeaux may be called the city of cellars, every conceivable space underground being utilised for the storing of wine, and it may be imagined what immense stocks there are. The city lies at the southern extremity of the Médoc but is situated in the upper part of the Graves district. In Bordeaux the expression "*vin blanc et rouge*" means white and red wine produced in the districts shown on the map and lying around the city. The Médoc is less inland than the other districts and, in fact, is situated between the sea and the broad estuary of the Gironde and hence the word Médoc is probably a contraction of "*In Medio Aquæ*." In places this estuary is more than five miles wide. On the east side of the estuary and northwards lies the Charente Inférieure, bordering in its turn on the famous brandy-producing district, the Charente, with Cognac as its centre. By

far the greater number of châteaux are situated in the Médoc which is the most productive area and certainly the wines of the Médoc are the most widely known. Mention need not be made of Châteaux Lafite, Margaux, Latour, Pontet-Canet, Mouton, Léoville, and so on, which are close to the towns either St. Julien or Pauillac (the Gravesend, so to speak, the Gironde). There are thousands of minor châteaux devoted to the production of good wine, the quality varying according to the district in which the wine is produced. It is very remarkable to notice how sharply a district bearing superior wine is marked from a district bearing inferior wine. The districts may, in fact, be contiguous but there is no doubt of the difference in the quality of the wine produced in each vineyard, though they are almost adjoin. The quality of a wine is, in fact, dependent upon soil and this varies considerably, even in the same districts. It is still the custom of the wine industry in the Médoc to adhere to a classification of "growths" which was drawn up very many years ago and which has been again upon as official and as a sort of hall-mark, and it is generally conceded that the division is a convenient one as regards standardising wines. It cannot be denied, however, that with improved attention to methods of cultivation during recent years growths placed outside this classification are called *superior bourgeois* or *simply bourgeois* really take a place in the list, especially as this grouping into classes was made so long ago. Certainly several of the unclassified wines run the classified wines very closely regards flavour and delicacy and amongst the former many excellent cheap wines (from 12s. to 24s. a dozen) are in this country.

The classification is as follows and next to the name of the château is given the name of the locality in which it is situated:—

FIRST GROWTHS (PREMIERS CRUS).

Château Lafite, Pauillac	Château Margaux, Margaux
Château Latour	"

SECOND GROWTHS (SECONDS CRUS).

Château Mouton Rothschild, Pauillac	Château Gruaud-Larose, St. Julien
" Rauzan-Ségla, Margaux	" Brane-Cantenac
" Rauzan-Gassies	" Cantenac
" Léoville-Lascases, St. Julien	" Pichon-Longueville, Pauillac
" Léoville-Barton, St. Julien	" Pichon-Lalande, Pauillac
" Léoville Poyferré, St. Julien	" Ducru-Beaucailhou, St. Julien
" Durfort-Vivens, Margaux	" Cos-d'Estournel, St. Estèphe
" Lascombes	" Montrose, St. Estèphe
" Gruaud-Larose-Sarget, St. Julien	"

THIRD GROWTHS (TROISIÈMES CRUS).

Château Giscours, Labarde	Château Palmer, Cantenac
" Kirwan, Cantenac	" La Lagune, Ludon
" d'Issan	" Desmirail, Margaux
" Lagrange, St. Julien	" Calon Ségur, St. Estèphe
" Lango	" Ferrière, Margaux
" Malescot-Saint-Exupéry, Margaux	" Marquis d'Almeida, Becker, Margaux
" Cantenac-Brown, Cantenac	"

FOURTH GROWTHS (QUATRIÈMES CRUS).

Château Saint-Pierre-Sevalstre, St. Julien	Château Pouget, Cantenac
" Saint-Pierre-Bontemps, St. Julien	" Latour-Carnet, St. Laurent
" Branaire-Ducru, St. Julien	" Rochet, St. Estèphe
" Talbot, St. Julien	" Beycheville, St. Julien
" Dubart-Milon, Pauillac	" Marguès-de-Termes, St. Julien
"	" Le Prieur, Cantenac

FIFTH GROWTHS (CINQUIÈMES CRUS).

Château Pontet-Canet, Pauillac	Château Le-Terre, Arzac
" Batallay	" Haut-Bages, Pauillac
" Grand-Puy-Lacoste, Pauillac	" Pédasclaux
" Grand-Puy-Ducasse, Pauillac	" Belgrave, St. Laurent
" Lynch-Bages, Pauillac	" Camensac
" Lynch-Moussas	" Cos-Labory, St. Estèphe
" Dauzac, Labarde	" Calve-Croizet-Bages, Pauillac
" Mouton-d'Armailhacq, Pauillac	" Cantemerle, Margaux

the whole it varies but little either on one side or the other of 10 per cent. by weight or 12·40 per cent. by volume. The extractive matters in claret are, as a rule, a fairly constant quantity, averaging 2·55 per cent. The figure is somewhat lower for old wines, while it is a little higher for the St. Emilion and Graves wines. Wines of delicate character, as a rule, seldom contain more than 2·50 per cent. of solid matters in solution. The average amount of glycerine in clarets is 0·642 per cent., but the amount varies in accordance with the nature of the wine, the maximum, as a rule, being just short of 1 per cent. and the minimum 0·43 per cent. The wines from the St. Estèphe district are generally characterised by containing the highest quantity—i.e., over 0·9 per cent. This is an interesting feature of St. Estèphe wines and almost serves, in our experience, as a hall mark. Whenever we purchased in the open market, and we obtained several samples in this way, a wine described as St. Estèphe, it always showed this relatively high proportion of glycerine. In old wines the glycerine is likely to

colour, as a rule, show a relatively small proportion of nitrogenous substances and *vice versa*, and in a wine decolourised by animal charcoal there is practically no nitrogen at all. The wines showing the highest proportion of nitrogenous bodies were No. 3 and No. 10 in Table A, and these showed the highest intensity of colour. On the other hand, the wine showing the smallest amount of nitrogen—namely, No. 1 in the table—showed the least intensity of colour. The nitrogen diminishes again in old wines due to loss by deposition and their colour is correspondingly reduced. The inference is that in red wines the nitrogen is part and parcel of, at any rate, some of the colouring constituents and it is of interest to add that the grape skin contains 1·45 per cent. of nitrogen which, calculated as albuminoid, amounts to 9·14 per cent. The average amount of albuminoid ($N \times 6·3$) in claret is 0·278, extreme points being 0·395 and 0·105. We shall return to this question of the amount of nitrogenous constituents present in wine, since they appear to affect the digestibility of wine in direct proportion to their amount

FIG. 3.

The press and vat-house.

exceed 0·5 or 0·7 per cent. Glycerine is, of course, a perfectly normal product of various fermentation and is probably a contributory factor to the preservation and conditioning of a wine and as well tending to give it body and sweetness. The chief preservative in wine, however, must be the alcohol, since de-alcoholised wine rapidly changes and gets mouldy. The sugar in clarets is practically constant, rarely exceeding 0·2 per cent., the average being as low as 0·130 per cent. Clarets contain, as a rule, less sugar than do white wines. Tannin is also a fairly constant quantity and averages 0·235 per cent. The amount is reduced by age or by fining. There appears, however, to be no relation between the amount of tannin and nitrogenous substances in a wine. The tannin, colouring matter, and nitrogenous substances share one common property in wine, since when red wine is decolourised with animal charcoal all three are found to be practically absent in the colourless wine.

The amounts of nitrogenous matters in claret vary somewhat widely and a relation seems to exist directly between the total nitrogen and the intensity of colour. Wines of low

and, as a rule, as colour diminishes the less is the interference caused by the wine with the digestive processes. It would follow that the young highly coloured wines are less digestible than the old wines in which the colour has largely disappeared. There are, however, other factors in the composition of wine as we shall presently see which may discount such a deduction or the idea of any relationship existing between colour and digestibility.

It is curious that claret is so often regarded as an acid or a sour wine. As a matter of fact it is the least acid of all wines and is certainly less acid than white wine. Claret is the "driest" of wines, there being practically no sugar present to disguise the small degree of acidity that exists. The palatability of sparkling wines such as champagne is considerably diminished when the wine is excessively dry and they appear intensely acid when the sugar is entirely removed. Of course, claret easily becomes sour if it is not securely corked or when the means to keep it away from the oxidising action of the air is defective. A good delicate mature claret will not keep; young, rough, vigorous wine, on the other hand, will

making of claret is there any recourse to the use of artificial agents and genuine claret is never fortified by the addition of spirit. In short, as we have said, claret is the simplest type of wine and the product of purely natural agencies, requiring no additions whatever to fit it for consumption or to adapt it to the public taste.

The red wines in the Graves district are produced much in the same simple way, as is also white claret (made from white grapes), while in the Sauternes district the method of wine making is totally different. The white grape of the Sauternes is allowed to get thoroughly ripe until, in fact, it shows signs of wrinkling up and rotting and consequently the vintage is later than in the Médoc. The grapes are picked with very great care and discrimination off the bunch singly grape by grape and after a thin mould has formed upon them. In the press house they are first trodden under foot and then by machinery, the expressed juice being collected and put straight into the hogshead in which the fermentation takes place, which generally lasts several weeks. The wine becomes bright and fermentation is arrested partly by the alcohol generated and partly by the onset of the cold weather. The grape juice, as may be anticipated, is very rich in sugar and the best Sauternes are sweet, and unless certain precautions are taken, as by burning some sulphur in the casks, fermentation will readily start again on the slightest provocation. Wines for export are also "sulphured" otherwise the casks containing them would

would imply, and in wine are also found, besides alcohol, the additional products of fermentation, such as glycerine, ethers, and higher alcohols. Moreover, as the alcohol develops it exerts a solvent action on the extractive matters of the skin and thus tannin and colouring matter appear in the wine. A sample of grape juice taken in the Médoc during the 1905 vintage gave the following results (grammes per 100 cubic centimetres) on analysis in THE LANCET Laboratory. Side by side with this analysis is placed an average analysis of a Médoc wine. A comparison of the two shows broadly the changes in composition effected by fermentation.

The Composition of Grape Juice compared with Wine.

	Grape Juice.	Claret.
Total solid matters	23.12	2.55
Sugar	21.60	0.13

Carting the grapes.

burst. There are, however, some very agreeable dry wines produced also in the Sauternes, but the most famous, as that of Yquem, are sweet, full, and generous and carry a high perfume. We deal with the character and composition of these wines in a section devoted to their analysis further on.

It may be added, in concluding this description of the wine-making processes of the Gironde, that no attempt is made to keep the processes away from public scrutiny and anyone is at liberty to visit the *cuvier* during the busy time of pressing the grapes; indeed, the entire operations during vintage, as during the harvest of corn in England, may be watched in detail from the roadway, and there are scores of presshouses opening on to the highway from which the pressing of the grapes may be seen as well as the processes involved in the consignment of the juice to the vats.

THE COMPOSITION OF THE WINES OF THE GIRONDE.

Millions of gallons of grape juice would be annually wasted if fermentation did not step in, which it does the moment the juice is set free from the fruit and preserves it in the form of wine. Fermentation may therefore be regarded as a preserving process in which the development of alcohol corresponding to the amount of sugar present in the juice is the chief factor. Broadly speaking, wine is grape juice with the sugar replaced by alcohol. The process of fermentation is, however, more complex than this statement

It should be added that the grape juice, previously to its despatch to THE LANCET Laboratory, was sterilised by heating immediately it left the press and certain albuminoid matters, gums, &c., had coagulated. These were collected, dried, and weighed, the sediment amounting to 1.02 grammes per 100 cubic centimetres of juice. The sediment contained mineral matter, 15.64 per cent.; albuminoid matters, 16.06 per cent.; and gums, fibre, and acids, 68.36 per cent. The coagulum obtained on sterilising grape juice bears a close resemblance to the composition of wine lees. The juice was slightly tinged red and contained merely traces of tannin.

The normal composition of genuine clarets is shown in Table A. The specimens were secured personally in Bordeaux by our Commissioner and an attempt was made to select types representative of the various districts shown in the map. They include the red wines grown in the districts of St. Estèphe, Pauillac, Margaux, St. Julien, Cantenac, and Labarde in the Médoc, Pessac and Léognan in the Graves district, and Pomerol and St. Emilion in the St. Emilion district. From time to time a considerable number of analyses of claret have been published in English scientific journals but hitherto these analyses have omitted certain important items which the present analyses supply, we believe, for the first time.

The results may be briefly summarised. The alcohol in claret rarely exceeds 10 per cent. by weight and on

TABLE D.—ANALYSES OF WHITE WINES.
(Results in Grammes per 100 c.c.)

Description.	Alcohol by weight.	Alcohol by volume.	Water.	Extractives.	Glycerine.	Sugar.	Tannin.	Protoid = N x 6.3.	Total volatile acidity as acetic acid.	Total fixed acidity as tartaric acid.	Potassium tartrate.	Total mineral matter.	Observations.
Château de Tastes. 1. Sauternes	12.55	15.66	83.60	17.50	0.633	14.000	Trace	0.356	0.090	0.45	0.339	0.35	A sweet wine with exquisite flavour.
Château de Rayne. 2. Sauternes	12.31	15.21	77.49	10.10	0.729	7.200	Trace	0.652	0.141	0.40	0.158	0.33	Less sweet than the previous wine but with excellent æsthetic qualities.
Petites Graves	8.71	10.22	83.84	2.45	0.541	0.23	Trace	0.141	0.135	0.73	0.109	0.23	A "dry," "clean" wine and of light alcoholic strength.
Grand Sec. 4. 1st Vin de Graves	11.47	14.18	85.23	2.25	0.603	0.240	Trace	0.243	0.120	0.63	0.079	0.20	A very agreeable wine with delicate flavour.

last for days after it has been poured out of the bottle. This serves as a simple but correct way of differentiating a wine of delicate character from a coarse one. The amount of fixed acidity in clarets expressed in terms of tartaric acid seldom exceeds 0.45 per cent., the average being 0.40 per cent., and in a sound wine the volatile acidity reckoned as acetic acid is seldom more than 0.17 per cent., the average being 0.127 per cent. The amount of potassium tartrate in claret is fairly constant also, the average being 0.166 per cent. It increases in full-bodied wines. The mineral matter varies between limits of 0.10 and 0.30 per cent. Summing up, it may be stated that, generally speaking, clarets, even from different districts, show a fairly uniform composition, and the small variations that are seen to occur may be accounted for by the special circumstances in which the wine is produced, as to whether it is old, delicate, full-bodied, coarse, highly or thinly coloured, and so forth. The generous and somewhat full character

in Table B. Besides those given in the table we have purchased many other samples which were submitted not to analysis but to the palate of an expert who pronounced them all to be wines possessing the genuine Bordeaux characteristics, though in some instances his opinion was qualified by such remarks as "perfectly genuine wine but not of great quality," "thin wine," "somewhat coarse," and so on, but all were described correctly as claret—that is, wine produced in the Médoc and other districts of the Gironde. Moreover, the price in some instances was not more than 12s. a dozen, comprising samples of really good *vin ordinaire*, while quite good claret with delicacy and bouquet and attractive flavour was purchased at from 15s. to 30s. a dozen.

On the whole it is satisfactory and gratifying to be able to report that the public get what they ask for when they purchase claret. There are, however, exceptions which we will point out although if our observations are followed there

TABLE A.—ANALYSES OF GENUINE CLARETS.

(Results in Grammes per 100 c.c.)

Description.	Alcohol by weight.	Alcohol by volume.	Water.	Extractives.	Glycerine.	Sugar.	Tannin.	Protoid = N x 6.3.	Total volatile acidity as acetic acid.	Total fixed acidity as tartaric acid.	Probable real tartaric acid.*	Potassium tartrate.	Total mineral matter.

* This column gives the total acidity less that due to tannic acid.

of a St. Estèphe, a red Graves, or a St. Emilion wine (the last being often called the burgundy of the Gironde) has its counterpart in a slight increase in alcoholic strength, in the amount of extractives, tannin, nitrogenous bodies and intensity of colour. The delicate wines, on the other hand, show a less robust constitution even from an analytical point of view. It is, however, chiefly the æsthetic qualities of a wine which give it the greatest esteem and up to the present chemical analysis can throw little light upon those elements which determine the fragrance, bouquet, and flavour of a wine. The estimation of the secondary products of fermentation (higher alcohols, ethers, and aldehydes) gives, however, some interesting results, as will be seen further on.

Having presented what may be regarded as the normal results of analysis given by clarets which we know to be genuine, we may next proceed to apply the same methods to the examination of wines described as clarets bought in the open market. The analytical results will be found

should be no difficulty in avoiding these exceptions. It should be stated that when purchasing these samples which proved to be genuine we made no special endeavour to procure samples which were suspicious either by being sold at an absurdly low price, say at 6s. a bottle, or by bearing a label which conveyed nothing. Later, however, we turned our attention to abnormally cheap wines and we found that for the most part these were being sold at cheap Italian restaurants. We append the analysis of samples in Table C. We are convinced that even many of these are genuine wines inasmuch as they are made from grape juice, not, however, in the Médoc but most probably in London. They are, in fact, the so-called "basis wines." As will be readily seen from the analysis, they are characterised by a high amount of alcohol (due to added spirit), high sugar and low tannin, low nitrogen and feeble colour. In some cases the addition of glycerine is obvious. Grape juice contains little tannin and, of course, is white in colour. The colour of the basis wine may be derived from a small

basis wines to which it is probable that glycerine is sometimes added.

SOME EXPERIMENTS BEARING UPON THE EFFECTS OF CLARET ON THE CHEMICAL PROCESS OF DIGESTION.

In recording the results showing the effects of claret and other wines upon the processes of digestion it should be stated that the present experiments were of a purely chemical and not physiological kind. That is to say, the experiments were conducted *in vitro*, employing artificial gastric juice and pancreatic juice respectively. Nevertheless, the results are of comparative interest as indicating at any rate the influence of wine and of claret in particular on the chemical process of digestion. Whatever may be the effect shown in experiments conducted *in vitro*, it must be remembered that *in vivo* good wine has a favourable influence upon the gastric function, which would, it is not unlikely, more than compensate for any discrepancy seen to exist in an experiment in which the effect of wine upon the merely hydrolysing action of a ferment—pepsin or pancreatin—is tried. It is generally conceded that the net result of a moderate use of wines, and especially light wines, with meals is favourable because they induce an increase of appetite and gastric secretion, and thus it is conceivable that even if the mere chemical process of digestion is interfered with at all such interference would be completely balanced by the healthy stimulus given to the gastric function. Upon this effect of wines is, in fact, based their use in health and disease. It will be seen from Table F that light natural clarets have only a trifling inhibitory and practically negligible effect upon the chemical activity of the gastric ferment, while there is a small retarding influence in the case of pancreatic digestion. Apparently those clarets which are of a light delicate character retard the processes of chemical digestion least, and in this category we must, of course, place the older "classed" wines. Nevertheless, wines of the *vin ordinaire* type show only a small disturbing effect upon digestion, an effect which probably is not produced at all in the living organism owing to the stimulating action of wine on the gastric function. In Table G also are included the results of two experiments with a solution containing amounts of tannin occurring in different clarets. Contrary to expectation, these solutions showed practically no inhibitory effect on the digestion of albumin. According to this the tannin of red wine would not appear to interfere with the process of digestion and in this connexion it may be called to mind that an ordinary cupful of tea contains a good deal more tannin than does an equal volume of claret. Also in the same table the results are shown of the effects on digestion of pure grape juice grown in the Médoc. Here there is evidently a marked inhibitory action which is diminished, however, as the grape juice is diluted with water.

When the activity of pepsin is interfered with at all by red wines it is generally due, we find, to the colouring matter of the wine, for as the intensity of the colour increases so is the inhibitory effect of the wine upon the chemical process of digestion increased. And when the colour of the wine is taken out with animal charcoal we found (see number 18 in Table F) that the decolourised wine has no appreciably interfering effect at all upon the digestive process. As already pointed out, animal charcoal extracts from wine its colouring matters, its nitrogenous bodies, and its tannin, and since the nitrogenous bodies increase directly with the intensity of the colour and tannin has very little effect upon the digestive process, it would appear that the chief constituent of red wine that is inhibitory to the chemical process of digestion is a nitrogenous body closely associated with the colouring matter. This result is very interesting as tending to indicate that old wines with low intensity of colour and delicacy of character are, from the point of view of dietetics, better than young, robust, highly coloured wines. On the other hand, old wines are richer in volatile bodies other than alcohol, such as ethers and higher alcohols, than are young wines, and in some cases, at any rate, these bodies seem to have a slight retarding influence on the digestive process. Colour being absent in white wines these when of a light character have a smaller inhibitory effect as a rule than red wines. Lastly, when a claret was distilled and the resulting weak spirit from it made up to the original volume of the claret and added to digestive agents there

was practically no retarding effect. The distillate so tested was of the same alcoholic strength as the claret—i.e., 10 per cent.—and contained, of course, the volatile constituents of the wine, the colouring matters, &c., being left behind in the still. The actual result is shown in Table G. On the whole, therefore, we conclude that claret,

addition of a highly coloured wine or from the skins of other fruits. If wine is defined to be the fermented juice of the grape then such preparations may be entitled to the designation of wine, but it is obviously misleading to label them Bordeaux or Médoc wine as is invariably done and in some instances the name of a hypothetical château is printed on the label. Shippers and agents would materially protect the public against this form of fraud if they would make it a universal rule to have affixed to the bottle a label with some kind of guarantee printed upon it in the form of the name of the producer, importer, or agent. The importation of grape juice of course avoids the spirit duties and we are surprised that the revenue authorities do not take action summarily in the matter, since by this device they are deprived of so much duty on wine made necessarily from material imported from abroad. In any case, such wines should be labelled compulsorily with the words "British made." It should be mentioned, however, that a vigorous and successful action has been recently inaugurated against the sale of fraudulent wines of the class described and in Bordeaux a powerful "syndicate of defence," comprising some of the largest wine growers in France, has been formed with the view of protecting the public against this species of imposition.

As we have said, however, the result of our inquiry has shown that the proportion of mis-named wines offered to the public as compared with the genuine article is exceedingly small and suspicion, having regard to the duties on foreign wines, will easily fall on a so-called genuine Médoc which claims to be valued at a little over 6*s.* a bottle. But perfectly good, wholesome, genuine Médoc wine is obtainable at 1*s.* per bottle which, while bearing the characteristics of a Bordeaux wine, is simple in kind and somewhat short of the æsthetic qualities of more expensive wines. The price of a wine is, of course, entirely dependent on these qualities: it is flavour that is paid for in the case of wine, just as it is in so many other articles of consumption. The palate rules the price, but wine is wine after all. The cheaper clarets are produced in the north of the Médoc, in the islands of the Gironde, in the districts around Blaye, on the east bank of the Gironde, and from the "Palus" or low-lying districts, and are commonly drinkable in the second year. They are sound, wholesome wines of the bourgeois type and, of course, less delicate than the "classed" wines produced in the localities of Pauillac, St. Julien, or Margaux.

The land of white claret is chiefly the renowned district of Sauternes, though a considerable amount of white wines is grown in the bordering district of Graves. Strictly speaking, "vin des Graves" applies to those wines, both red and white, produced in the Graves district, although in this country the designation "Graves" nearly always implies a white wine. White claret is more often vin des Sauternes grown in the neighbourhood of Barsac, Priegnac, and Bommes. The composition of the wines of the Sauternes district shows wide variations, chiefly in regard to alcohol and sugar, and depends upon the variations in the quality of the grape. Broadly, there are three descriptions of wine—the very sweet (almost syrupy wines, recalling Tokay), the moderately sweet, and the dry. Examples of all three are given in Table D. As will be seen, the chief point of difference in the composition of a red and a white wine is the practical absence of tannin and colour in the latter, the juice being fermented after the removal of the skins. The "dry" wines in other respects resemble red wines, the amount of sugar, alcohol, and acidity, however, being in general higher while the percentage of albuminoids is lower consistently, as it were, with the absence of red colour. A somewhat high proportion of glycerine in the full, sweet wines will be observed to increase *pari passu* with the increased alcoholic strength. The sweet wines also contain a relatively high percentage of albuminoids.

We may next call attention to Table E in which the amounts of ethers, higher alcohols, and aldehydes in the various wines of the Gironde are compared. We believe that this is the first time that the analysis of wines has referred to these constituents and the results are of interest, first of all in showing that the higher alcohols and ethers in the wine are most frequently present in much the same ratio as in brandy—which if genuine is the distillate of wine in a simple still; and secondly, the amount of higher alcohols present increases with the age of the wine and when they occur in relatively large proportion the indication is generally in

favour of a heavy full-bodied wine. The full sweet Sauternes, for example No. 15, contain as much as 500 grammes of higher alcohols per 100 litres of alcohol present and a high figure is also reached by the dry Sauternes, while the average of a number of light clarets is between 160 and 109 grammes per 100 litres of alcohol present, a figure which is given by ordinary genuine brandies. The somewhat heavy character of Sauternes apart from

their relatively high alcoholic strength is probably in part due to the development of alcohols of the higher series. The ethers in Sauternes wines are, again, generally speaking, higher in amount than in the Médoc wines. The aldehydes vary but little, the highest (St. Emilion wine) being 7.00 and the lowest (an old Latour wine) 3.50. In certain instances a high proportion of higher alcohols corresponds with a relatively high amount of glycerine except in the case of wines of doubtful origin or

section and the others which we have quoted bearing upon the same subject, we should be inclined to say that unqualified practice and the sale of drugs by unqualified persons are alike forbidden in the Transvaal in such terms that the most ingenious quack should find even the registered company fraud insufficient to protect him.

The regulations framed by the Transvaal Medical Council for midwives naturally call for less comment than the Ordinance, affecting as they do a matter of less wide importance. They also appear not to differ in general principles from those framed by the Central Midwives Board, although variations in matters of detail might easily be found and noted for consideration whenever the last-named body proceeds to revise and to amend its rules in the light of its own experience and that of others. We observe, however, that the midwife already in practice has more stringent conditions to comply with in the Transvaal than with us and that the general fitness of the midwife for her position as apart from her training has been the subject of considerable solicitude to the Medical Council. In the case both of the existing midwife and of the one who asks for registration on the ground that she has received an education qualifying her to fulfil her duties the same condition obtains with regard to her character—that it must be attested by "a magistrate, or a minister of religion, or a medical practitioner of this colony;" and, again, her personal health is deemed to be of sufficient importance to her patients for a certificate to be demanded "signed by a registered medical practitioner in this colony to the effect that the applicant's state of health is such that no danger to her patients would be involved by her admission to practice as a certificated midwife." Both these rules, it will be observed, tend to render the medical profession at large responsible jointly with the Council and in co-operation with it for the selection of suitable women as midwives and the inclusion of trained nurses under the jurisdiction of the Medical Council will also be noted. The regulations affecting these accompany those relating to midwives and in these also the registered medical practitioner is prominent upon the list of those whose testimonial to the nurse's health and personal character is necessary.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

A COMMITTEE was held on Jan. 25th, Sir RICHARD DOUGLAS POWELL, Bart., K.C.V.O., the President, being in the chair. The PRESIDENT announced that the Council had appointed Captain Leonard Rogers, I.M.S., as Milroy lecturer for 1907, and that he had selected as his subject Kala-azar, its Differentiation and Etiology.

The following gentlemen having passed the required examination were admitted as Members of the College: Joseph Arthur Arkwright, M.D. Cantab., L.R.C.P. Lond.; William Carnegie Brown, M.D. Aberd.; and Robert Fielding-Ould, M.A., M.D. Oxon.

Licences to practise physic were granted to 100 gentlemen who had passed the necessary examination.

Diplomas in Public Health were granted jointly with the Royal College of Surgeons of England to the following gentlemen: Amellus Cyril Birt, L.R.C.P. Lond., M.R.C.S. Eng.; Henry Caird, M.B., Ch.B. Edin.; Herbert Chesson, L.R.C.P. Lond., M.R.C.S. Eng.; John Moore Collins, M.B. Lond., L.R.C.P. Lond., M.R.C.S. Eng.; Gerald Corcoran, L.R.C.P. & S. Ire.; James Gilkes, M.B., C.M. Edin.; Captain Frederick Harvey, R.A.M.C., L.R.C.P. Lond., M.R.C.S. Eng.; L.S.A.; George Haylett Lock, L.R.C.P. Lond., M.R.C.S. Eng.; Greer Edmund Malcolmson, M.D. Lond.; Percy Knowles Maspratt, M.B., B.S. Cantab., L.R.C.P. Lond., M.R.C.S. Eng.; John Ford Northcott, M.D. Lond., L.R.C.P. Lond., M.R.C.S. Eng.; Owen Herbert Peters, M.B., Ch.B. Melb.; Lieutenant John William Symth Seccombe, R.A.M.C., L.R.C.P. Lond., M.R.C.S. Eng.; Frank Blenkinsopp Skerrett, M.B. Lond., L.R.C.P. Lond., M.R.C.S. Eng.; Captain Lessel Philip Stephen, I.M.S., M.B., Ch.B. Aberd.; Philip Graham Storr, L.R.C.P. Lond., M.R.C.S. Eng.; Lieutenant-Colonel Thomas David Winter, R.A.M.C., M.R.C.S. Eng., L.S.A.; and Cyril Haworth Wright, M.B., Ch.B. Edin.

The following communications were received: 1. From the Secretary of State for the Colonies (Jan. 11th) in reply to the Registrar's letter informing him of the steps taken by

the Royal Colleges in the matter of tropical medicine. The letter was as follows:—

Downing-street, Jan. 11th, 1906.

DEAR SIR—I am directed by the Earl of Eglinton to acknowledge the receipt of your letter of the 3rd instant and to state that his lordship has perused it with interest and has learnt with satisfaction the arrangements which are being made by the Royal College of Physicians of London and the Royal College of Surgeons of England for the recognition of tropical medicine.

I am, Sir, your obedient servant,

The Registrar, Royal College of Physicians. FRED. GRAHAM.

2. From the Royal Sanitary Institute, inviting the College to appoint delegates to attend the congress of the institute at Bristol from July 9th to 14th, 1906. The invitation was accepted. The PRESIDENT nominated Dr. H. Handford as one of the delegates and the nomination of a second delegate was postponed. 3. From the secretary of the Royal College of Surgeons of England reporting some of the proceedings of its Council on Jan. 11th. 4. From the director of the Whitechapel Art Gallery thanking the College for its promised loan of pictures for March and April.

The PRESIDENT and the TREASURER drew attention to the portrait of His Majesty the King by Luke Fildes, R.A. The portrait had been procured partly by the surplus of money received for the seating arrangements for viewing the Coronation procession and partly by subscription.

On the nomination of the Council the following Fellows were elected councillors: Professor W. Osler, Dr. H. Radcliffe Crocker, Dr. H. B. Toth, and Dr. T. D. Acland.

Dr. F. H. CHAMPNEYS moved the following proposition, which was seconded by the SECOND CENSOR (Dr. NORMAN MOORE):—

That a committee be appointed to examine and report on the curriculum in midwifery and diseases of women. That the committee consist of all obstetric physicians and assistant obstetric physicians of the London medical schools who are Fellows of the College, with power to add to their number.

On the motion of Dr. L. E. SHAW, seconded by the THIRD CENSOR (Dr. FREDERICK TAYLOR), the following words were added to the proposition: "With the addition of four Fellows who have been deans of medical schools." The proposition was carried and the following four Fellows were nominated to serve on the committee in consequence of Dr. Shaw's proposal: Dr. H. G. Turner, Dr. R. H. P. Crawford, Dr. J. Fawcett, and Dr. A. Latham.

Dr. C. Theodore Williams was re-elected as a representative of the College on the Court of Governors of the University of Birmingham for three years from Jan. 1st, 1906.

Dr. Champneys was re-appointed as a representative of the College on the Central Midwives Board for one year from March 31st next.

The quarterly report of the College finance committee, dated Jan. 11th, 1906, was received and adopted.

A report was received and adopted from the representative of the College on the General Medical Council (Dr. Norman Moore) concerning the meetings in November and December, 1905.

A report from the committee of management dated Dec. 18th, 1905, was received and adopted. The report recommended that the course of laboratory instruction in public health at the Royal Institute of Public Health, London, should be recognised as fulfilling the requirements of regulations for Part I. of the examination for the diploma in Public Health.

A second report from the same, dated Jan. 4th, was received and adopted. It was based on the following reference from the Royal College of Surgeons of May 11th last:—

That it be referred to the committee of management to consider and report as to the desirability of treating chemistry, physics, and biology as subjects of preliminary education and of requiring that an examination in these subjects should be passed before the recognition of the commencement of medical studies; and to further report as to the desirability of the two Colleges approaching the University and other examining bodies with a view to adopting a five years' curriculum of professional study from the date of passing the preliminary science examination.

The report was a very full and elaborate one and the conclusions arrived at were as follows:—

1. That it is undesirable to treat chemistry, physics, and biology as subjects of preliminary education. 2. That it is undesirable to require an examination in chemistry, physics, and biology to be passed before the commencement of medical studies; and to further report as to the desirability of the two Colleges approaching the University and other examining bodies with a view to adopting a five years' curriculum of professional study from the date of passing the preliminary science examination.

in the matter of lighting, whilst the water-supply and general arrangements for washing are better than they used to be on this class of boat. But these are the only words of commendation that in most cases can be used. Practically all the vessels which come into the Port of London with immigrants are foreign vessels, and it is certain that some of these are in a very insanitary condition and offer the most inadequate accommodation to their wretched living freight. The sexes are mixed, there is inadequate lavatory provision, and, to speak generally, the state of some of these ships may be described as simply filthy. In this connexion the nationality of the incomers must be borne in mind and too much blame must not be attributed to those responsible for the state of the vessels. The class of immigrants to Great Britain is, on the whole, bad, though it is no worse now than it used to be. The majority of those who come to London are Polish Jews or Jews from Eastern Europe. Looking back to the statistics of 1904 we find that of 82,848 aliens known to have settled in Great Britain 46,095 were either Russians or Poles and at least a similar ratio of nationalities is being maintained. They are, as a rule, of indifferent physique, wretchedly poor, and unclean in their habits, and however good the quarters offered them might be at the beginning of the voyage, short as that voyage usually is they may be trusted to foul their nest. With regard to their poverty they are supposed to be in possession of £5 before permission is given to enter the country, but this regulation since the Act became law has been on many occasions waived, mainly on the immigrant proffering the plea that he was the victim of religious persecution in Russia. There are, however, more rejections made for economical reasons than for physical disabilities.

Transmigrants having prepaid tickets are not liable to medical inspection or general inquisition at the immigration ports of Great Britain but opportunity is always taken for medical examination lest there should be among these people any disease coming within the meaning of the Public Health Act.

THE MEDICAL PROFESSION IN THE TRANSVAAL.

WE recently dealt with the regulations for medical practice in the Orange River Colony¹ and we now have before us a copy of the Ordinance enacted in 1904 in the Transvaal "for the registration of medical practitioners, dentists, chemists and druggists, midwives and nurses, and for the better regulation of medical practice and the sale and dispensing of drugs, medicines, and poisons," and also a copy of the regulations for midwives and trained nurses framed under the Ordinance by the Transvaal Medical Council which it has called into being. Of the precise date upon which by the proclamation of the Lieutenant-Governor the main portion of the Ordinance came, or will come, into force we are not aware, but the section which provided for the constitution of the Transvaal Medical Council, and of the Transvaal Pharmacy Board became operative at once, and the regulations for midwives referred to are a sample of the industry of the former body. The council consists of eight medical practitioners and two dentists, six of the former and one of the latter being elected by their brother practitioners and the others being appointed by the Lieutenant-Governor, who has to nominate as one of the medical members the medical officer of health of the colony. The board consists of one member of the council deputed by it to act and of five chemists and druggists, two of them appointed by the Lieutenant-Governor and the other three elected.

Both the Ordinance and the regulations for midwives are of interest to the medical profession in England because they must be deemed to have been the work of their brethren in a great and new colony who have based them upon corresponding laws and regulations in England or have studied these and have declined to adapt portions of them to their own use. In the Transvaal Ordinance a point of difference from the English law arises from the natural circumstances of a colony, so that we find provision for the admission to practice of medical men and dentists holding the degrees,

diplomas, or certificates of foreign or colonial universities or medical schools. These are to be granted certificates subject to conditions securing their efficiency, with a further requirement of proof "that by the laws of the country in which such degree or diploma was conferred, British subjects legally qualified to practise as medical practitioners or dentists in Great Britain and Ireland are afforded privileges equivalent to those granted by registration under the Ordinance," a form of reciprocity to which the most ardent advocate of free trade in commercial matters should not object.

In the portion of the Ordinance which relates to pharmacy and to the sale of poisons we note a section which provides severe penalties not only for any "medical practitioner, chemist and druggist, veterinary surgeon, or other person entitled to keep or sell poisons" who shall contravene the regulations relating to these, but also for any person thus defined "who shall sell or keep for sale by himself or any apprentice, servant, or agent any medicines or drugs of bad quality." Generally speaking, the sale of poisons is to be conducted upon similar lines to those followed in England—that is to say, a schedule divided into two parts is appended to the Ordinance in which various poisons are entered, with provision for the addition of others when required, the one part of the schedule containing names of poisons which must not be sold unless the purchaser is known to, or introduced to, the seller and in the case of which full particulars of the sale have to be recorded, the second part containing those for which a label will be sufficient bearing the name of the article, the word "poison," and the name of the seller. It is interesting to note in this connexion the consideration given by the Transvaal legislature to the sale of vermin-killers containing poison. A divisional court recently held² that a compound known as "Rankin's ointment" sold for the destruction of vermin in the human hair must be classed in Part II. of the schedule of poisons as a vermin-killer, although it contains a poison which sold by itself would come under the provisions of Part I., there being special mention of poisons compounded for use as vermin-killers in Part II. and no mention of them in Part I. The Transvaal Ordinance has anticipated the difficulty which was not foreseen in England when vermin-killers were placed specifically in Part II., for it says in Part II. of its schedule that "vermin-killers, compounds containing poisons prepared for the destruction of vermin, if not subject to the provisions of Part I. are in Part II.," and it definitely includes vermin-killers in Part I. if these are preparations of poisons subject to Part I. when uncompounded. This is certainly better than to allow drugs so dangerous that their sale is to be guarded specially when they are pure to be sold with the mere protection of the label when they are associated with other substances and are ostensibly sold for an apparently harmless purpose.

The most important feature, however, of the Transvaal Ordinance in the opinion of many will be the introduction in the colonial law of the provision which it appears useless to hope for in the mother country that no person "shall be entitled to practise as a medical practitioner or dentist unless he has obtained a registration certificate," coupled with a section forbidding the illegal use of medical titles in terms similar to those to which we are accustomed but better calculated to cover the cases which are likely to arise. No less interesting to us also is a section which orders that "no society or association of persons who are not registered under this Ordinance may use the descriptions or titles provided herein nor may any company incorporated by law carry on the business of chemist and druggist unless the managing director of such company is a duly registered chemist and druggist and unless the name of the assistant, who himself must be qualified under this Ordinance, managing such shop or other place in which the business is carried on by the company is conspicuously posted in such shop or place; provided that anything which would be an offence under this Ordinance if committed by an individual shall be an offence by every director of a company if committed by such company; provided, further, that nothing in this section shall be held to prevent the employment by any such registered dentist or chemist and druggist, as the case may be, of an unqualified assistant or assistants for the purpose of mechanical dental work or of compounding drugs and dispensing medicines under his personal supervision." Subject to any questions of detail which may arise in the process of enforcing this

Looking Back.

FROM

THE LANCET, SATURDAY, Feb. 2nd, 1828.

MIDWIFERY seems to have made less progress in Ireland, than in any other part of the British empire. By this observation, we do not mean that there have not been at all times, in Dublin, and in the principal towns of the provinces, men competent to the application of obstetric science in the most efficient manner; we only mean to assert, that the number of practitioners, writers and teachers, has been less in proportion to the population, the wants of students, and the general mass of the profession of that country, than in either England or Scotland. Until very lately, there were many districts in the island, to the extent of twenty or thirty miles in circumference, in which no practitioner of midwifery resided; and where, in consequence of this deficiency, the most melancholy cases have occurred without the aid of art being attainable. Its medical literature cannot yet exhibit a single treatise in use among students, or even known as a work of reference in this branch of science; while Britain, both north and south, has been profuse in productions of this description. We need scarcely quote the names of Hunter, Denman, Blundell, Davis, Burns, and Hamilton, as a contrast to the Clarkes, Evorys, and Labatts of Dublin—men, who, though highly distinguished as accoucheurs, have left no record of their experience to profit posterity, or to exempt their country from the imputation of defective authorship. It may surprise our English and Scottish readers still more, when we assure them that, in a city so large as Dublin, and a school where there are so many prosecuting their studies, there are but two professors of midwifery, and these by no means comparatively well attended. In the University, or School of Physic, there is no professorship of this kind existing; the College of Surgeons very properly founded one, but owing to the neglect of the gentleman appointed, and still more to the want of a clinical establishment for the illustration of his precepts, his lectures, which, indeed, were but seldom delivered, were all but entirely neglected; the Lying-in Hospital, for causes which we shall immediately point out, is but ill-calculated to realise the objects of a school of midwifery; and to supply this defect of obstetrical instruction, there is not a single private teacher of the art, that we are aware of, in the Irish capital.

MEDALS TO MERITORIOUS STUDENTS.

THE custom of distributing prizes or rewards to the most intelligent students, is, we are glad to see, now coming into general use. It is a practice which, in our estimation, is calculated to call forth a noble spirit of emulation and generous rivalry amongst the medical pupils, and, consequently, has our warmest approbation.

On Thursday so-night, Dr. Hopkins's prize, a splendid gold medal, was presented in the Webb-street Theatre, to Mr. ROBERT CORBIN, being the successful candidate for the best essay on the "Nature and Treatment of Protracted Labour."

On the following Saturday, the silver medal was given to Mr. W. BLOXAM for the second best essay on the same subject. The prizes were not adjudged until after the parties had undergone a rigorous public examination, in which they were called upon to defend every point of their theses, thus affording a farther guarantee of their competency. The gold medal is of considerable value, and is a beautiful specimen of art: on one side is a device both classical and apposite—Juno, the reputed patroness of child-birth, is seen with her peacocks watching over a female who is reclining upon a couch, having apparently been recently delivered. A female attendant is kneeling and holding in her arms a new-born infant. On the reverse of the medal is a Latin inscription, expressive of the object for which the medal was given. In confirmation of the beneficial results which we have said are likely to arise from this public mode of rewarding students, we may here mention the fact, that at St. Thomas's Hospital, where Mr. Green has offered a medal for the best set of clinical reports, a spirit of emulation and inquiry has been manifested amongst many of the medical students, which it is truly gratifying to witness. To adopt a homely phrase,—every man is put upon his mettle.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8891 births and 4834 deaths were registered during the week ending Jan. 27th. The annual rate of mortality in these towns, which had been 18.3, 16.7, and 15.8 per 1000 in the three preceding weeks, rose again to 15.9 per 1000 last week. In London the death-rate was 15.3 per 1000, while it averaged 16.2 per 1000 in the 76 other large towns. The lowest death-rates in these towns were 8.1 in Smethwick, 9.2 in West Ham, 10.0 in Northampton, 10.8 in Bournemouth, 11.4 in Hornsey and in Aston Manor, and 11.5 in King's Norton; the highest rates were 20.8 in Stockton-on-Tees, 21.1 in Liverpool, 21.5 in Stockport, 21.6 in Sunderland, 23.2 in Tynemouth, 23.8 in Great Yarmouth, and 24.6 in Preston. The 4834 deaths in these towns last week included 385 which were referred to the principal infectious diseases, against 464, 389, and 369 in the three preceding weeks; of these 385 deaths, 110 resulted from whooping-cough, 93 from measles, 73 from diphtheria, 46 from scarlet fever, 45 from diarrhoea, and 18 from "fever" (principally enteric), but not any from small-pox. In Brighton, Norwich, St. Helens, Huddersfield, Cardiff, and ten other smaller towns no deaths from any of the principal infectious diseases were registered last week, while they caused the highest death-rates in Wolverhampton, West Bromwich, Aston Manor, Leicester, Stockport, Burnley, Preston, Leeds, and West Hartlepool. The greatest proportional mortality from measles occurred in Wolverhampton, Aston Manor, Preston, and Leeds; from scarlet fever in West Hartlepool; from diphtheria in Hornsey and Merthyr Tydfil; from whooping-cough in Birmingham, Aston Manor, Leicester, Stockport, and Burnley; and from "fever" in West Bromwich. No death from small-pox was registered last week in any of the 76 towns, and no case of this disease was under treatment last week in the Metropolitan Asylums Hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital on Saturday last, Jan. 27th, was 2923, against 3299, 3062, and 3066 on the three preceding Saturdays; 322 new cases were admitted during the week, against 291, 257, and 328 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 434, 370, and 299 in the three preceding weeks, further declined last week to 293 and were 120 below the average number in the corresponding periods of the four preceding years. The causes of 48, or 1.0 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Leicester, Nottingham, Salford, Leeds, Hull, Newcastle-on-Tyne, and 45 other smaller towns; while the largest proportions of uncertified deaths were registered in Portsmouth, King's Norton, Liverpool, St. Helen's, Warrington, Blackburn, Sunderland, South Shields, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 19.8, 17.8, and 18.2 per 1000 in the three preceding weeks, further rose to 19.6 per 1000 during the week ending Jan. 27th, and was 3.7 per 1000 in excess of the mean rate during the same period in the 76 large English towns. Among these Scotch towns the death-rates ranged from 14.6 in Aberdeen and 17.0 in Leith, to 21.1 in Perth and 29.7 in Dundee. The 670 deaths in these towns included 31 which were referred to measles, 13 to diarrhoea, 12 to diphtheria, seven to whooping-cough, four to "fever," and two to scarlet fever. In all, 69 deaths resulted from these principal infectious diseases last week, against 80, 61, and 53 in the three preceding weeks. These 69 deaths were equal to an annual rate of 2.0 per 1000, which was 0.7 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of measles, which had been 33, 28, and 24 in the three preceding weeks, rose again last week to 31, of which 25 occurred in Glasgow, three in Dundee, and two in Paisley. The deaths from diarrhoea, which had been 20, 16, and 19 in the three preceding weeks, further declined to 13 last week, and included seven in Glasgow and two in Dundee. The fatal cases of diphtheria, which

The PRESIDENT then dissolved the Comitia.

Further evidence of the occurrence of a chronic toxæmia had been found by Dr. Ainslie who examined numerous arteries from various parts of the body and found that a condition of chronic endarteritis was constant and often extremely well marked, though irregular in distribution even in cases of general paralysis in which senility could be excluded. About the same time Dr. D. Chalmers Watson had advanced very similar views regarding the pathogenesis of tabes dorsalis. In 1902 the lecturer, along with Dr. G. Douglas McRae and Dr. J. Jeffrey, had commenced a bacteriological research. They found that a diphtheroid bacillus was specially prominent in the gastro-intestinal and respiratory tracts in cases of general paralysis and that a similar organism could frequently be isolated from the brain. They advanced the hypothesis that general paralysis of the insane was the result of a chronic toxic infection from the respiratory and alimentary tracts, permitted by general and local impairment of the defences against bacteria and dependent upon the excessive development of various bacterial forms but especially upon the abundant growth of a Klebs-Löffler bacillus of modified virulence which gave the disease its special paralytic character. In their later investigations Dr. McRae and he had simply been putting this hypothesis to the test and every step forward had been

chair.

A letter from the Clerk of the Privy Council was read transmitting a copy of a resolution passed by the guardians of the Lutterworth union suggesting the reduction from 20 to seven of the number of midwifery cases qualifying a candidate to enter for the Board's examinations. The answer of the Board was that it did not approve of the suggested reduction. A communication was received from Dr. A. J. Wallace asking for the opinion of the Board as to his right in certain circumstances to refuse to sign the certificate of instruction required under the regulations from candidates entering for the Board's examinations. After some discussion it was determined that it was outside the jurisdiction of the Board to decide whether anyone was bound to certify and an answer to that effect was directed to be sent to Dr. Wallace. A letter was then read from Dr. T. Eustace Hill, county medical officer of Durham, as to the extent of the exemption conferred by Rule E 21. This rule provides that nothing in Section E of the rules framed under the Midwives Act "shall apply to certified midwives exercising their calling in hospitals, work-houses, or Poor-law infirmaries under the supervision of a duly appointed medical officer." Section E contains the rules for regulating, supervising, and restricting within due limits the practice of midwives. The reply of the Board to Dr. Hill was to refer him to the Midwives Act and to the rules framed under it in accordance with that part of Section 3 of the Act dealing with the duties and powers of the Board.

In the University, or School of Physic, there is no professorship of this kind existing; the College of Surgeons very properly founded one, but owing to the neglect of the gentleman appointed, and still more to the want of a clinical establishment for the illustration of his precepts, his lectures, which, indeed, were but seldom delivered, were all but entirely neglected; the Lying-in Hospital, for causes which we shall immediately point out, is but ill-calculated to realise the objects of a school of midwifery; and to supply this defect of obstetrical instruction, there is not a single private teacher of the art, that we are aware of, in the Irish capital.

MEDALS TO MERITORIOUS STUDENTS.

THE custom of distributing prizes or rewards to the most intelligent students, is, we are glad to see, now coming into general use. It is a practice which, in our estimation, is calculated to call forth a noble spirit of emulation and generous rivalry amongst the medical pupils, and, consequently, has our warmest approbation.

On Thursday se'night, Dr. Hopkins's prize, a splendid gold medal, was presented in the Webb-street Theatre, to Mr. ROBERT CONNIX, being the successful candidate for the best essay on the "Nature and Treatment of Protracted Labour."

On the following Saturday, the silver medal was given to Mr. W. BLOXAM for the second best essay on the same subject. The prizes were not adjudged until after the parties had undergone a rigorous public examination, in which they were called upon to defend every point of their theories, thus affording a further guarantee of their competency. The gold medal is of considerable value, and is a beautiful specimen of art: on one side is a device both classical and apposite, Juno, the reputed patroness of child-birth, is seen with her peacocks watching over a female who is reclining upon a couch, having apparently been recently delivered. A female attendant is kneeling and holding in her arms a newborn infant. On the reverse of the medal is a Latin inscription, expressive of the object for which the medal was given. In confirmation of the beneficial results which we have said are likely to arise from this public mode of rewarding students, we may here mention the fact, that at St. Thomas's Hospital, where Mr. Green had the honour to be the first of clinical reports, a great deal of observation and inquiry has been manifested amongst many of the surgical students, which it is truly gratifying to witness. To adopt a timely plan, every case is put up on a stand.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8391 births and 4834 deaths were registered during the week ending Jan. 27th. The annual rate of mortality in these towns, which had been 18.3, 16.7, and 15.8 per 1000 in the three preceding weeks, rose again to 15.9 per 1000 last week. In London the death-rate was 15.3 per 1000, while it averaged 16.2 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 8.1 in Smethwick, 9.2 in West Ham, 10.0 in Northampton, 10.8 in Bournemouth, 11.4 in Hornsey and in Aston Manor, and 11.5 in King's Norton; the highest rates were 20.8 in Stockton-on-Tees, 21.1 in Liverpool, 21.5 in Stockport, 21.6 in Sunderland, 22.2 in Tyne-mouth, 23.8 in Great Yarmouth, and 24.6 in Preston. The 4834 deaths in these towns last week included 385 which were referred to the principal infectious diseases, against 464, 369, and 559 in the three preceding weeks; of these 385 deaths, 110 resulted from whooping-cough, 93 from measles, 73 from diphtheria, 46 from scarlet fever, 45 from diarrhoea, and 18 from "fever" (principally enteric), but not any from small-pox. In Brighton, Norwich, St. Helens, Huddersfield, Cardiff, and ten other smaller towns no deaths from any of the principal infectious diseases were registered last week, while they caused the highest death-rates in Wolverhampton, West Bromwich, Aston Manor, Leicester, Stockport, Burnley, Preston, Leeds, and West Hartlepool. The greatest proportional mortality from measles occurred in Wolverhampton, Aston Manor, Preston, and Leeds; from scarlet fever in West Hartlepool; from diphtheria in Hornsey and Merthyr Tydfil; from whooping-cough in Birmingham, Aston Manor, Leicester, Stockport, and Burnley; and from "fever" in West Bromwich. No death from small-pox was registered last week in any of the 76 towns, and no case of this disease was under treatment last week in the Metropolitan Asylums Hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital on Saturday last, Jan. 27th, was 2923, against 3299, 3062, and 3066 on the three preceding Saturdays; 322 new cases were admitted during the week, against 291, 257, and 328 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 454, 370, and 299 in the three preceding weeks, further declined last week to 293 and were 120 below the average number in the corresponding periods of the four preceding years. The causes of 48, or 1.0 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Leicester, Nottingham, Salford, Leeds, Hull, Newcastle-on-Tyne, and 45 other smaller towns; while the largest proportions of uncertified deaths were registered in Portsmouth, King's Norton, Liverpool, St. Helen's, Warrington, Blackburn, Sunderland, South Shields, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 19.8, 17.8, and 18.2 per 1000 in the three preceding weeks, further rose to 19.6 per 1000 during the week ending Jan. 27th, and was 3.7 per 1000 in excess of the mean rate during the same period in the 76 large English towns. Among these Scotch towns the death-rates ranged from 14.6 in Aberdeen and 17.0 in Leith, to 21.1 in Perth and 29.7 in Dundee. The 670 deaths in these towns included 31 which were referred to measles, 18 to diarrhoea, 12 to diphtheria, seven to whooping-cough, four to "fever," and two to scarlet fever. In all, 63 deaths resulted from these principal infectious diseases last week, against 60, 61, and 53 in the three preceding weeks. These 63 deaths were equal to an annual rate of 2.0 per 1000, which was 0.7 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of measles, which had been 33, 23, and 24 in the three preceding weeks, rose again last week to 31, of which 25 occurred in Glasgow, three in Dundee, and two in Paisley. The deaths from diarrhoea, which had been 20, 16, and 19 in the three preceding weeks, further declined to 13 last week, and included seven in Glasgow and two in Dundee. The fatal cases of diphtheria, which

had been 13, eight, and five in the three preceding weeks, rose again last week to 12, of which eight were registered in Glasgow, two in Edinburgh, and two in Dundee. The deaths from whooping-cough, which had been 11, five, and two in the three preceding weeks, rose again to seven last week, and included four in Glasgow and two in Dundee. Of the four fatal cases of "fever" two were recorded in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 136, 126, and 114 in the three preceding weeks, further declined last week to 110, and were 53 below the number in the corresponding period of last year. The causes of 28, or more than 4 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 21·7, 21·7, and 20·1 per 1000 in the three preceding weeks, rose again to 21·2 per 1000 during the week ending Jan. 27th. During the past four weeks the death-rate has averaged 21·2 per 1000, the rates during the same period being 16·9 in London and 18·3 in Edinburgh. The 154 deaths of persons belonging to Dublin registered during the week under notice were eight in excess of the number in the preceding week and included five which were referred to the principal infectious diseases; of these, three resulted from diarrhoea, and one each from diphtheria and whooping-cough, but not any from small-pox, measles, or "fever." These five deaths were equal to an annual rate of 0·7 per 1000, the death-rates last week from the principal infectious diseases being 1·5 in London and 0·8 in Edinburgh. The fatal cases of diarrhoea, which had been one in each of the three preceding weeks, increased last week to three. The 154 deaths in Dublin last week included 23 of children under one year of age and 51 of persons aged 60 years and upwards; the deaths of infants showed a slight decline from the number recorded in the preceding week, while those of elderly persons showed a considerable excess. Eight inquest cases and eight deaths from violence were registered, and 70, or nearly half, of the deaths occurred in public institutions. The causes of six, or nearly 4 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet-Surgeon F. W. Stericker to the *Dryad*, Staff Surgeon J. K. Robinson to the *Nisibe*. Surgeons: P. W. MacVean to the *Skirmisher* (lent); M. W. Haydon to the *Adventure* (lent); R. S. Osborne to the *President*, for three months' course of hospital study; A. la T. Darley to the *Ganges* for *Donscarven II.*; J. Stoddart to the *Pembroke*; L. C. Robinson to the *Foreright*; and G. O. M. Dickenson to the *Forward* (lent).

In accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1881, Inspector-General of Hospitals and Fleets Richard William Coppinger has been placed on the Retired List at his own request (dated Jan. 25th, 1906).

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel J. M. F. Shine is appointed Officer Commanding Station Hospital, Deesa. Colonel O. A. Webb is appointed Administrative Medical Officer at Cork and Colonel Martin is appointed Principal Medical Officer, Welsh and Midland Command. Lieutenant-Colonel C. W. Thiele, Lieutenant-Colonel T. B. Winter, Captain P. G. Hyde, Lieutenant R. E. Humsfrey, Lieutenant G. G. Tabuteau, Lieutenant W. Parsons, and Lieutenant C. W. O'Brien have left England for duty in India.

INDIAN MEDICAL SERVICE.

Surgeon-General Lionel D. Spencer, C.B., retired, to be Honorary Surgeon to the King, vice Surgeon-General J. M. Cunningham, C.S.I., deceased (dated Jan. 27th, 1906). Major W. Molesworth, who has been on the staff of Lord Amphill in India, is selected to serve as medical officer to Sir Arthur Lawley on his taking up his duties as Governor of Madras.

The following gentlemen were successful at the examination for admission to the Indian Medical Service held on Jan. 23rd and four following days:—

Names.	Marks.	Names.	Marks.
H. W. Pierpoint	3761	R. H. Lee	3377
W. D. H. Stevenson	3543	G. E. Malcolmson	3113
H. P. Cook	3510	F. P. Wernicke	3111
P. S. Mills	3501	P. Heffernan	3053
H. G. Gharpurey	3492	W. A. Meams	3023
W. J. Fraser	3451	D. M. C. Church	3021
D. C. V. Fitz Gerald	3353	S. T. Crump	3014
C. R. O'Brien	3318	H. S. Hutcheon	2836
R. S. Kennedy	3252	R. G. G. O'Leary	334
C. A. Godson	3249	W. B. A. K. Cullen	223
B. Hithani	3248	J. McG. Skinner	297
N. H. Hume	3222		

44 candidates (29 of whom had university degrees) competed for the 23 vacancies. 18 of the successful candidates possessed university degrees.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant Algernon E. L. Wear to be Surgeon-Captain (dated Jan. 16th, 1906).

DEATHS IN THE SERVICES.

Surgeon-General William Frederick de Fabek, I.M.S., retired, on Jan. 18th, at his residence in London, in his seventy-second year. He entered the service as assistant surgeon in 1857, was promoted surgeon in 1869, surgeon-major in 1873, brigade surgeon in 1885, deputy surgeon-general in 1886, and retired with the rank of surgeon-general in May, 1890. He was present at the siege of Sevastopol in the Crimean war of 1854-55 and was at the assault on the Redan (medal with clasp). He also served in the Indian Mutiny, 1857-58 (medal).

ARMY MATTERS IN GENERAL.

No little consideration has been given of late to the discussion of army schemes in general and to the most suitable organisation in particular of our land forces for the purposes of home defence. All that the new Secretary of State for War has so far said and done has tended to justify the expectations which his appointment has raised. Everybody hopes that some really adequate and practicable measure may be the final outcome of all that has of late years been taking place at the War Office. Lord Roberts, who is evidently deeply impressed with the gravity of the situation and indefatigable in his efforts to make the nation realise it, has also been recently speaking at Liverpool in advocacy of his views; and a proposal to hold a schoolboys' rifle meeting at Bisley has met with a generous response from headmasters and is likely to be carried to a practical conclusion. So that it will not be from any lack of zeal and activity in various directions if we fail to reach some desired end. It is stated that among other changes in the near future there is to be an increase in the auxiliary branches of the Royal Army Medical Corps. What we desire to see, however, is that in connexion with any forthcoming big scheme of reorganisation the subject of our sanitary and field medical arrangements for war should also be taken up and considered. Meanwhile, everyone feels that the new War Minister is quite right not to be hurried in his attempt to accomplish the extremely difficult task which he is undertaking. So far as his speeches at Edinburgh, his concessions to the Volunteers, and his assurance that the Government is not likely "to do anything that would tamper with the efficiency of the army or navy" are concerned, there cannot well be any ground for dissatisfaction. It is needless to say that the next Army Estimates will be unusually interesting and instructive.

LORD ROBERTS AND SIR FREDERICK TREVES AT MANCHESTER ON THE ADVANTAGES OF ARMY TRAINING.

Lord Roberts in prosecution of his patriotic undertaking in the matter of Imperial defence addressed a meeting at Manchester on Jan. 30th in which he dwelt upon the practical and other advantages to be derived from such national and other training as he had been so strenuously advocating. We are very glad to notice that he was strongly supported on that occasion by Sir Frederick Treves on the grounds of national health. There is no need to call attention to the views published from time to time in these columns on the subject but we may add that, in our belief, Sir Frederick Treves was giving expression to an opinion generally held by members of the medical profession regarding the salutary effect which such a movement as this

advocated by Lord Roberts might have upon the physical condition of the people. Sir Frederick Treves, in the course of his remarks, said that the report of the Commission on Physical Degeneration was not very pleasant. It contained signs and hints of something that was coming, a weakness in our race, which if not paid heed to must lead to that degeneration which most of them feared. In his opinion the most striking feature of the age was the effect on the nervous system of the conditions of our modern life. The best remedy for this was perfect physical health, such as was gained by open-air exercise. That could be obtained by the system of military training suggested by Lord Roberts.

The *Broad Arrow* states that the administration of hospital services hitherto performed by the Royal Engineers has been handed over to the Director of Barrack Construction to whom, or to his representatives, should be addressed all communications respecting hospital buildings and their accessories which have until now been forwarded to the Royal Engineers.

Correspondence.

"And aliter partem."

ENTERIC FEVER IN THE ARMY.

To the Editors of THE LANCET.

SIRS.—Although most medical men who saw service at the front in South Africa recognise the impossibility of sterilising all water used either by boiling, filtering, or the addition of chemicals in tablet form (carefully elaborated and prescribed by armchair hygienic authorities on the prevention of enteric fever in a campaign), all will agree that, wherever possible, every opportunity should be taken to get the men to obtain water which has been boiled. Whilst serving with General Plumer's force I had occasion to remark that the Australians and New Zealanders preferred to eat and every halting place to drink tea. When a lime juice ration was served out very often they would not drink it. It was once or twice suggested that a double ration of tea would not only have given greater comfort to the soldiers but also have insured double the quantity of water being boiled. Thus they were always ready to fill their water bottles with tea before trekking. At the end of each day's trek it was a common sight to see them h-mantle a farm house to obtain firewood to boil the "billy." Had full advantage been taken of this property to drink tea I was convinced the incidence of enteric fever would probably have been less. However, experience bore out that this was not so. The worst attack of enteric fever that the New Zealanders and Queenslanders with Plumer had was after a rest of two weeks just outside of Wakkerstroom, where they availed themselves of the opportunity of getting copious supplies of tea from the food force parties. However, as previous to the night at Onverwacht, after which we went into Wakkerstroom to rest, we had been out more than three or four days in a standing camp, we did not have the opportunity of exposing the force to the danger arising from a lengthy residence near its own or another soldier's excrement. Consequently (unless the epidemic of enteric fever was carried by "the filthy foot of a black-fellow"), my idea that it was best for each section of four to boil their own water—and to encourage them to do so—should have given them more tea—was not put out of court by the Wakkerstroom experience.

Boiling of boiled water it is necessary to remember that water is not very insipid. Also my experience was that the men and even the medical officers, when really tired, often from thirst (similar to that so graphically described by the late George Sayers in "With Kitchener to Khartoum") preferred to drink water, not only else was possible. Until that time was when I once never turned about the people's divers of enteric fever and dysentery. The boiling out of Portland filters to each company was an experiment which, with our colour, was not a success, owing probably to the fact that we had no special facilities to get to look after the sanitation of the troops. In the later stages of the war, after often 100 miles of march, by night with stripped camp, and no wheel transport were out on patrol, each man was left with a rifle and three last-bills, the only chance of getting a drink of boiled water was from a "billy" (in which

each section of four generally made tea). For large standing camps and troops at the base it has long been known that the best method of treating water is to boil it.

For the benefit of those who seem to claim some originality for the idea I may mention that on the first page of Xenophon's *Anabasis*, Book II., reference is made to the using of the captured wagons, shields, &c., as firewood with which to boil the water for the 10,000. However, for mounted infantry and cavalry out on patrol, night marching, and doing work such as we did in South Africa, it was simply impossible to carry out sterilisation of the water on a large scale. It is worthy of note that in the irregular corps many of the men over thirty suffered less from enteric fever than the young regulars and the more youthful members of their own corps. Speaking for the New Zealanders and Queenslanders, the elder men were also able to withstand the wear and tear of the campaign better. Also their keenness for active service was not one whit less than that of the young bloods. From what I saw in South Africa and have since read I should think that inoculation against enteric fever, the taking of quinine if exposed to malaria or dengue fever (as we were in the Bushveldt and Pongola), the plentiful supply of soap, the frequent fresh issues of underclothing to prevent the miseries caused by body lice, together with instruction by the medical officers on the transports as to simple lines of health, the provision of special sanitary orderlies for each company, an expert sanitary officer attached to the staff to disengage the chief staff officer from selecting an old camping ground, also to point out the advantage of a frequent change of camp, and the necessity of filling in latrines, would go far to reduce the incidence of enteric fever, dysentery, and other preventable diseases.

I am, Sirs, yours faithfully,

J. S. FURDY, M.D., C.M. Aberd., D.P.H. Cantab., F.R.G.S.

Late Surgeon-Captain New Zealand Militia.
Port Said, Jan. 10th, 1905.

THE PREVALENCE OF CONTAGIOUS DISEASE: A SUGGESTED INQUIRY.

To the Editors of THE LANCET.

SIRS.—During the past 20 years I have lived more abroad than in England and have noticed that amongst Americans, Colonials, Germans, and Japanese there is a curious unanimity of opinion that the modern British islander is degenerating. Some well-educated Germans have told me that one of the main causes of the decay of the Spaniards and the Portuguese was the prevalence of "specific" disease and intimated that the same cause is deteriorating the British race. It is all very well to laugh at these thoughtless foreigners and to ascribe their views to envy and prejudice but every year our population becomes more and more urban and a larger proportion thereby come in contact with contagious disease. Is it therefore possible that the British are commencing to show the effects of the *spirochaeta pallida*? Permit me to suggest that the medical profession should endeavour to get a return for a period of three months of all cases treated at 12 of the largest hospitals in the kingdom, the direct or indirect cause of which is considered to be contagious disease. A return of this character would not cost much money and could commence on any date convenient to the hospital; the result might be of national importance and could not fail to be of interest to the medical profession.—I am, Sirs, yours faithfully,

H. N. ROBINSON, M.R.C.S. Eng., L.R.C.P. Lond.
Jr. of Constitutional Clinic, Piccadilly, W., Jan. 25th, 1905.

THE HEALTH OF MADEIRA.

To the Editors of THE LANCET.

SIRS.—As reports have been disseminated to the effect that either bubonic plague or some other infectious disease is prevalent in Madeira it is advisable that the medical profession should be informed that these rumours are absolutely without foundation. Some six weeks ago several so-called suspicious cases were removed to the "Lazareto," a building used for isolating cases liable to spread infection, the persons who had been in contact with these patients being also removed and isolated in a separate part of the same building. Shortly afterwards it began to be said (rightly or wrongly) that these isolated individuals were not receiving that care

and attention which were necessary; the "lazareto" was in consequence stormed by the populace which had always doubted the genuineness of the existence of infectious disease. The inmates were found to be healthy with the exception of five patients who were suffering from more or less trivial ailments, and since this occurrence there have been no further cases of so-called plague. It turns out that the whole affair has been a scare purposely got up by certain interested individuals in Madeira from political motives which need not be considered further.

I write this with the full concurrence of the senior English physician in the island, Dr. M. O. Grabham, and we both wish not only to reassure the friends of visitors at present staying here but to make public the fact that intending visitors need have no fear of running any danger on their arrival.—I am, Sirs, yours faithfully,

J. GEDDES SCOTT, M.R.C.S. Eng., L.R.O.P. Lond.

Funchal, Madeira, Jan. 20th, 1906.

THE DIRECT REPRESENTATION OF SCOTLAND ON THE GENERAL MEDICAL COUNCIL.

To the Editors of THE LANCET.

SIRS,—Rumour has been asserting that I do not intend to be a candidate for the suffrages of Scottish practitioners at the next election in October of this year for the post of their Direct Representative. Will you kindly grant me the kind privilege of saying publicly that statements to that effect are untrue and misleading?—I am, Sirs, yours faithfully,

Dingwall, N.B., Jan. 24th, 1906.

WILLIAM BRUCE.

X RAY DOSAGE.

To the Editors of THE LANCET.

SIRS,—In the interesting article on two cases of leukaemia treated by x rays in THE LANCET of Jan. 27th, p. 211, Dr. W. Fronsidge Bruce regrets the indefinite manner in which the dosage of the rays is stated. I think, however, that more essential details are there noted than seems customary in the reports of x ray treatment.

For example, in Mr. A. Marmaduke Sheild's case of mammary cancer, recorded in THE LANCET of Nov. 18th, 1905, p. 1464, Dr. H. Lewis Jones in reporting the x ray treatment only tells us that the applications lasted 12 minutes, that the tubes were "soft" or "medium," and that the secondary current was 0.5 to 0.8 milliamperes. No mention is made of the strength of the primary current nor even of the distance of the tube from the diseased tissue. When it is considered that a tube at eight inches from the skin gives it more than twice the irradiation it would do at one foot, it is evident that the exact distance is an important datum. The capacity of the coil, the number of warts in its primary, the rate of interruptions, the particular "break" used, the distance of the tube and its equivalent spark gap, are all such important factors in the production and application of x rays that it seems a pity to omit any of them in reporting the treatment of a case.

As to the value of recording the milliamperage of the tube circuit with the instruments now made for that purpose, opinions seem to differ. From my own observation of the behaviour of an average milliamperemeter under varying conditions, I suspect they do little more than indicate their own eccentricities, and feel convinced that a far more accurate estimate of what the tube is yielding can be made from a consideration of the energy of the primary current in conjunction with the state of the tube and the frequency and efficiency of the interruptions.

I am, Sirs, yours faithfully,

Ballschullish, Jan. 29th, 1906.

W. D. ANDERSON.

PHYSIOLOGICAL TESTS FOR PHARMACEUTICAL PREPARATIONS.

To the Editors of THE LANCET.

SIRS,—May I trespass briefly on your space once more? My letter of Jan. 20th has served its main purpose by eliciting the information I desired, but it appears in part to have conveyed a not wholly correct impression of my attitude

towards this question. I do not think that I under-rate the importance of such pharmacological researches. My contention is simply this—that before accepted standards are officially remodelled we should have evidence as complete and irrefragable as possible that the older methods rightly carried out cannot be trusted to give a reasonable uniformity and I think that the evidence adduced by any investigator loses in weight if he cannot state that the preparation examined has been made under his own supervision from crude drugs which he personally admits to be the best obtainable, and it is because I hold this opinion that I attach great value to the definite statement in Dr. W. E. Dixon's courteous letter that he found a similar variation in preparations of ergot made by himself and Dr. Hayes. Now, if their experience is confirmed by other pharmacologists of equal standing, and if the same principle of procedure—viz., personal identification throughout—is applied to the other drugs in question with a like result, we shall have before us a clearer indication than we yet possess that with our present incomplete knowledge of the chemistry of such drugs further official tests are desirable; and it is quite possible that bio-chemical standardisation may prove to be the best means of securing that approach to constancy in therapeutical activity which is so important.

I am, Sirs, yours faithfully,

WILLIAM MARTIN, M.D. Durh.

Newcastle-upon-Tyne, Jan. 29th, 1906.

THE DOCTOR IN THE DOCK.

To the Editors of THE LANCET.

SIRS,—Under this title a correspondent recently called attention in your columns to the careless manner in which all sorts of miscreants are received by a badly edited press into the ranks of the medical profession. That colossal black-guard Bridgwater, and more recently a bogus Scotch "baron," were both called medical men in many of the voluminous notices of their exploits. A very good example of this is now occurring in the case of a person alleging himself to be a medical practitioner who was charged with a petty theft from a chemist's shop at Charing Cross. This man was described in newspaper after newspaper as a medical practitioner, but the magistrate very properly refused the application for bail made on his behalf by his solicitor when he heard that the accused was not a registered medical man. I am not prejudging this case. The accused is said to possess an American degree, a claim which, though it is made by every impudent quack, may in this case be perfectly sound; but until the man's medical status is proved it is obviously unfair to the medical profession to allude to him as a medical man. The *Times* says of this person that he "described himself as a medical practitioner," and such is evidently the fair method of reporting.

I suggest that the mental confusion of the average journalist upon what constitutes a medical practitioner is out of date. Not long ago every outburst of rowdiness in a restaurant or a music-hall was always attributed to medical students and I do not suppose that the various clerks and commercial employes, with possibly a leaven of legal and theological students, who are responsible for these little outbursts, have, or have ever had, the least intention to father their offences upon other people. It was a badly edited press which, with a mind reminiscent of Bob Sawyer and Joe Muff, felt constrained to attribute to the medical student all mischief done by any group of young men which included students of every sort. But the laborious life of the present medical student is becoming known and taproom émeutes are no longer attributed to him as a matter of course. The stage still suffers to some extent at the hands of the press, inebriated ladies of the pavement being not infrequently alluded to in the course of police reports as actresses; but here, again, the journalist is becoming better informed and the ordinary female "drunk" is now more often described as "alleging herself to be an actress." As justice is being done to our medical students and to our comediennesses and tragediennesses, is it not time that the press should awake to what gives a man a right to be described as a medical practitioner? A medical practitioner is a registered medical man in practice—not an advertising quack, not a transatlantic adventurer, nor a monger of abortion pills, and not as a rule either a common thief, common rogue, or common rascal.

I am, Sirs, yours faithfully,

T. DELORME.

Jan. 29th, 1906.

THE NATURE OF CANCER FROM THE CLINICAL ASPECT.

To the Editors of THE LANCET.

SIRS,—In his recent Bradshaw lecture Mr. H. T. Butler,¹ putting aside for the moment the problem of the exact mode of formation of a cancer, propounded the question, "How does a cancer act when it has once appeared in the body?" and he answered without hesitation, "It acts as a parasite," and he gives his reasons for his opinion. Whencesoever the cells have come that we see in a malignant growth, however much they may resemble the healthy cells, the cancer itself behaves as a parasite. Histologically no differences, or only very slight variations from the normal, can be seen between the unaffected healthy cells of the parts and the cells of the new growth; they may take the same stains, they may yield the same chemical products, but physiologically—that is, in the mode of action—they are wide as the poles asunder. The normal healthy cell of the part is a unit of the whole and in sickness or in health behaves as such. It is a citizen of a State and it does its part in carrying on the work of the State; its actions are dictated by a sense of the well-being of the whole and its own interests are subordinate to those of the community. As the whole body flourishes it flourishes also; should sickness and starvation overtake the body the normal cell suffers with it, but when returning health again blesses the whole body, the individual normal cell shows by its participation that it, too, is a lawful sharer in the joys and prosperity of the commonwealth. Finally, the term of life of the cell being ended it goes its way, leaving behind it nothing that will prove hurtful to the State. The ways of the malignant cell are far otherwise. Its ways are the ways of a parasite, and of a parasite which cares nothing for the life of its host. Its aim is to grow as rapidly as possible, with the least exertion, to batten on the body that contains it, and to disregard utterly all considerations as to the life of its entertainer, so that it does not even refrain from doing to death the being who has nourished it.

If this be a true description of the habits of a parasite, surely a cancer has a rightful claim to this title. Come its cells whence they may, whether as an invasion from outside or by a transformation or a degeneration of the living tissues of the body, it cannot be denied that a malignant growth is a true parasite. What matters to it the well-being of the body that contains it? The cancer grows apace. What matters to it that its host lights on days of poverty? Its growth does not slacken. The very prosperity of the cancer depends on what it steals from the body, and the failing health of its host seems but to serve to stimulate the demands and the growth of the cancer. Not until the long-suffering body sickens and dies does the guest relax its demands on its entertainer. It has done to death its benefactor and it must suffer death with it. Yet, even when death claims the body the cancer need not die. Experiments have shown that a malignant growth can be transplanted by transmission from one mouse to another until it has passed through the bodies of 30 mice, and yet at the end of this long series of transigrations it has maintained the same vitality and the same characters which it exhibited in the mouse in which it first was seen. That mouse has long since died but the same malignant growth still lives on. It is not, however, merely in its place of origin that a cancer acts like a parasite. Not only does it spread locally with a complete disregard for the tissues in which it lies, not only does it push aside, press upon, and destroy important structures of its host, careless of the harm it does but, like many parasites, it endeavours to disseminate itself throughout the body which contains it. Its cells are scattered broadcast in the lymph and the blood stream, and wherever one of the cells may lodge there arises a new structure of the cancer with cells of the same aspect and nature as in the spot where it was first seen. This new deposit of the cancer proceeds exactly like its progenitor; it grows with at least the same rapidity; it invades the surrounding tissues and structures at the expense of the host. Each new secondary growth of cancer becomes a centre whence further growth of cancer becomes a fact, not only the distant parts of the body but the remotest corners of the body of the patient limits the extension of the cancerous disease which the body may contain.

From its clinical aspect it cannot be denied that carcinoma is a parasitic disease. Mr. Butler could not doubt that the cells of the new growth were the descendants of the cells of the tissue where the growth first showed itself. He mentioned, merely to condemn the suggestion, that the cell of the new growth is the result of the assimilation of an extraneous cell to the cell of the part; the resemblance is too close for the possibility of this to be admitted, for we should have to acknowledge that the intrusive cell should come to resemble exactly the epithelial cell of the part where it chances to lodge, that amongst squamous cells it should be squamous, that amongst columnar cells it should become columnar, and that spheroidal cells should influence it to become spheroidal too. There only remains the possibility that the cells of the cancer are derived from the cells of the part. What change has taken place in them to induce them to adopt the parasitic attitude we cannot say. One suggestion not wanting in support is that the cell has undergone degeneration and in descending from its former high estate it has reverted to an ancestral form with greatly increased power of multiplication, but this reversion, this atavism, has unfitted it for taking part in the life of the body to which it originally belonged. It has entirely lost touch with its former comrades and it has become a stranger, and because a stranger a parasite, whose life henceforth will run on different lines; it will be dependent as of yore upon its host for sustenance but it will acknowledge no allegiance in return. This theory of reversion is pretty but it is unfortunate that it has at present but little basis of fact. The practical application for the surgeon of the recognition of the truth that, whatever its real origin, a carcinoma, once it has appeared, is a parasitic disease, jumps to the eyes. He will, as he has done for years, strive to remove utterly every cell of the new growth, and inasmuch as the outer limits of the growth are ill defined he will cut widely so as to insure that nothing has been left. The importance of an early operation will not need any insistence for him, he is at present fully alive to the value of removal of the primary growth while yet no truant cells have escaped to distant parts. There is, however, one lesson to be learned from a complete recognition of the parasitic nature of a malignant growth, and that is the danger of the infection during the operation of the tissues left behind. Every cell of the new growth can act as a spore of the disease. It will suffice to start a recurrence of the growth should it be left in the wound. If the scalpel in removing the growth should at any time cut through a portion of the tumour it may, and even probably will, become infected with some cancer cells, and if the same scalpel is used without sterilisation for the removal of the growth and cuts through healthy tissues these are likely to become infected with the cancer cells and recurrence in the wound or scar will occur. In this way, doubtless, are to be explained many of the recurrences in situ which occur after the removal of cancerous growths. It is to be noted that this explanation of the return of malignant growths is quite independent of any theory that carcinoma is due to a germ. Formerly it was not rare to see a surgeon incise a tumour of the breast to make certain of its nature and then, with the very same scalpel, he would proceed to excise it. The utmost care should be taken that the scalpel used for incising a new growth is not employed for excising it. By drawing attention to the parasitic nature of carcinoma when viewed from a clinical aspect Mr. Butler has done a distinct service to surgery. What the outcome may be of the investigations into the true etiology of cancer none can say but for the surgeon clinically it will ever be a parasitic disease.

I am, Sirs, yours faithfully,

Jan 26th, 1906.

CHURCHILL.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Bequests to Birmingham Hospitals.

A SUM of £20,000 bequeathed by the late Mrs. White to the Birmingham and Midland Hospital for Women has been the subject of litigation in the Chancery Division of the High Court of Justice. Under the will of the testatrix the sum was given towards the rebuilding and equipment of the hospital, the money to be applied to the satisfaction of, and under the direction of, the executors. The counsel for the next-of-kin contended that the enlargement of the hospital was entirely completed on the death of the testatrix and that

the gift of £20,000 was not necessary for the scheme to be carried out. Further, the executors had exercised no controlling influence and the counsel contended that no part of the bequest could be applied in payment of what had been already done. The counsel for the hospital stated that the sum of £12,885 was required for the purpose of completing the hospital at the date of the will. Mr. Justice Kekewich, in summing up, said that he could not construe the wording of the will to mean that the money was a free gift to be applied in any way the hospital authorities thought fit. Neither could he decide in the absence of the Attorney-General that so far as the specified object failed the gift might be treated as charitable. Further, he could not see that any time limit was fixed. He considered that the executors might liberally construe the words "rebuilding," and "equipment." When the hospital was both fully rebuilt and completely equipped the executors might find the full amount at their disposal was reasonably required for the purposes to which they might properly apply it and, on the other hand, it might be that they had a substantial balance. On their report he should be prepared to give directions but in the meantime the case was adjourned.—Under the will of Mr. William Robert Lane of Richmond Surrey, formerly of Birmingham, the Queen's Hospital, the General Hospital, and the Children's Hospital each receive £1000.

Local Charities.

The annual meeting of subscribers to the Midland Counties Home for Incurables was held under the presidency of the Marquis of Hertford, vice the late Lord Leigh. The committee reported that the ordinary revenue of the home had enabled it to maintain a higher average number of inmates than had ever been reached before and to create an additional free bed. The commencement of the new east wing was referred to with satisfaction; it will accommodate 15 additional patients and will entail an increased expense of £450 a year.—The annual report of the Worcester Ophthalmic Hospital recorded an increase of patients and of annual subscriptions. The expenditure had decreased.—The annual report of the Sands Cox Provident Dispensary showed an increase of members. It appears from the report and from the speeches made at the meeting that members made an average contribution of 3s. a year in return for which they could be attended by their own local medical man and by suitable trained nurses when required. The medical men in attendance received 5s. per member per year so that the dispensary partakes in a measure of the nature of a charity.

Local Drainage and Sewerage Scheme.

The scheme for constructing storm-water filters and for improving the present filters at Saltley, to which I referred in a former letter, has been considered and approved by the drainage board. The storm-water filters constructed on the principle of bacteria beds will be built of medium to be obtained from the gas and destructor works—viz., clinker and ashes. The efficiency of the present filter-beds will be increased by making the depth of the medium five feet and by providing silt tanks for freeing the sewage of suspended matter before distributing it on the beds. The cost will be spread over a series of years and the board hopes that the annual precepts need not be increased.

Falling Birth-rate in Birmingham.

The city medical officer of health in his quarterly report states that the number of births registered during the last three months of 1905 was the lowest on record for that period—viz., 3648 (birth-rate 26.9 per 1000), as compared with 4017 and 4078 in the fourth quarters of the two preceding years. The general birth-rate in Birmingham has been declining for a considerable number of years. The infant mortality rate is low; in only one ward did it exceed 200 per 1000 births, whereas in the fourth quarter of the preceding year it exceeded 200 in eight of the wards. The general mortality rate was also low; 16.3 per 1000; the highest mortality rate in any ward was 22 per 1000. The mortality rate due to the seven principal zymotic diseases was equal to 1.7 per 1000, as compared with 1.4 per 1000 in the preceding fourth quarter.

Care of Mentally Defective Children

The sites and buildings subcommittee of the Birmingham education committee has decided to adapt the old industrial school in Gem-street for the purposes of a special school for mentally defective children. At the last meeting of the Birmingham education committee Mrs.

Hume Pinsent, the chairman of the special schools subcommittee, was asked how parents received the decision that their children were mentally deficient and in the event of a parent not being satisfied whether there was, as it were, any court of appeal? In reply, Mrs. Pinsent stated that to the admission examination the parents were summoned, as well as the teacher of the child, His Majesty's Inspector, the chairman of the education committee, and the medical man who was examining. In 99 cases out of 100 no objection whatever was made by the parents. They frequently had parents bringing children and asking that they should be admitted to the schools. It was further stated that the subcommittee was waiting for the report of the Royal Commission which was now sitting before bringing forward any scheme for permanent boarding schools for these children.

Jan 30th

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Preston, a "Whited Sepulchre."

SUCH is the title given by one of the members of the Preston town council at its meeting on Jan 25th, when he said "it seemed as if they had not cast off the stigma of [being] the whited sepulchre of the north." For the last two months the death-rate has exceeded the birth rate, the town having passed through an epidemic of measles. Severe strictures were passed on the old women and "ignorant young mothers" by Dr. W. J. McDade as to their treatment of the children. Dr. Brown, the chairman of the health committee, attributed the high death-rate to the fact that Preston people "had been having their little fling" since Christmas began and "the disregard of health laws during the Christmas holidays is terrible." He said also that the people neglect "all the ordinary precautions of life, and we are now reaping the result in a mortality that is terrible to look on." The assemblies of children during the Christmas holidays helped to spread measles and "he attributed last week's death-rate of children of 433 per 1000 births to election madness," parents keeping their children up when they ought to have been in bed four or five hours. He thought it a disgrace that they had not "more regard to their children's lives." This shows a discreditable, and it may be said an inhuman, state of things in Preston, which may be said to be known as "proud Preston"; scarcely proud just now, one would think, of the children's death rate of 433 per 1000. The cotton trade, the chief provider of the industry of Lancashire, is said to be in a state of almost unexampled prosperity, of which it is having its share. It is a well-known fact, but not one to the credit of our working population, that in times of high wages the infant mortality is high, while in the hard times of the cotton famine during the American civil war the infant death-rate was very low. In Preston Dr. McDade attributed some part of the child slaughter to the ignorance of the young mothers, yet Preston has had the advantage, if it may be so called, of being taught in our elementary schools, but not, unfortunately, those things which go to form character and fit the young women to enter on family life prepared for their responsibilities. Dr. Brown spoke severely, but he is not one to use strong words without thought, and the mayor hoped that his remarks would have some effect. Perhaps after the excitement of the election is over some needed improvements in the elementary educational curriculum may be looked for.

Small-pox.

Small-pox still continues to be a trouble in this part of the world. Five fresh cases were reported some days ago at Oldham. The Manchester city council has agreed with the Levenshulme urban district authority to allow cases of small-pox from the district to be received at the Manchester corporation hospital. The town of Heywood has become notorious as the place where those who wish to gamble with the dangers to life and health and of disfigurement that small-pox so often leaves as a memento of its visitation are welcomed and sent forth rejoicing in the possession of a vaccination exemption certificate. It was not, therefore, very surprising to hear it called "the Mecca of the anti-vaccinators" by someone who applied the other day for such a certificate at the Bolton borough police court.

Appointment.

Dr. Duncan Forbes, who has been for some time assisting

the gift of £20,000 was not necessary for the scheme to be carried out. Further, the executors had exercised no controlling influence and the counsel contended that no part of the bequest could be applied in payment of what had been already done. The counsel for the hospital stated that the sum of £12,885 was required for the purpose of completing the hospital at the date of the will. Mr. Justice Kekewich, in summing up, said that he could not construe the wording of the will to mean that the money was a free gift to be applied in any way the hospital authorities thought fit. Neither could he decide in the absence of the Attorney-General that so far as the specified object failed, the gift might be treated as charitable. Further, he could not see that any time limit was fixed. He considered that the executors might liberally construe the words "rebuilding" and "equipment." When the hospital was both fully rebuilt and completely equipped the executors might find the full amount at their disposal was reasonably required for the purposes to which they might properly apply it and, on the other hand, it might be that they had a substantial balance. On their report he should be prepared to give directions but in the meantime the case was adjourned.—Under the will of Mr. William Robert Lane of Richmond Surrey, formerly of Birmingham, the Queen's Hospital, the General Hospital, and the Children's Hospital each receive £1000.

Local Charities.

The annual meeting of subscribers to the Midland Counties Home for Incurables was held under the presidency of the Marquis of Hertford, vice the late Lord Leigh. The committee reported that the ordinary revenue of the home had enabled it to maintain a higher average number of inmates than had ever been reached before and to create an additional free bed. The commencement of the new east wing was referred to with satisfaction; it will accommodate 15 additional patients and will entail an increased expense of £450 a year.—The annual report of the Worcester Ophthalmic Hospital recorded an increase of patients and of annual subscriptions. The expenditure had decreased.—The annual report of the Sands Cox Provident Dispensary showed an increase of members. It appears from the report and from the speeches made at the meeting that members made an average contribution of 3s. a year in return for which they could be attended by their own local medical man and by suitable trained nurses when required. The medical men in attendance received 6s. per member per year so that the dispensary partakes in a measure of the nature of a charity.

Local Drainage and Sewerage Scheme.

The scheme for constructing storm-water filters and for improving the present filters at Salfley, to which I referred in a former letter, has been considered and approved by the drainage board. The storm-water filters constructed on the principle of bacteria beds will be built of medium to be obtained from the gas and destructor works—viz., clinker and ashes. The efficiency of the present filter-beds will be increased by making the depth of the medium five feet and by providing silt tanks for freeing the sewage of suspended matter before distributing it on the beds. The cost will be spread over a series of years and the board hopes that the annual precepts need not be increased.

Falling Birth-rate in Birmingham.

The city medical officer of health in his quarterly report states that the number of births registered during the last three months of 1905 was the lowest on record for that period—viz., 3648 (birth-rate 26.9 per 1000), as compared with 4017 and 4078 in the fourth quarters of the two preceding years. The general birth-rate in Birmingham has been declining for a considerable number of years. The infant mortality rate is low; in only one ward did it exceed 200 per 1000 births, whereas in the fourth quarter of the preceding year it exceeded 200 in eight of the wards. The general mortality rate was also low, 16.3 per 1000; the highest mortality rate in any ward was 22 per 1000. The mortality rate due to the seven principal zymotic diseases was equal to 1.7 per 1000, as compared with 1.4 per 1000 in the preceding fourth quarter.

Care of Mentally Defective Children

The sites and buildings subcommittee of the Birmingham education committee has decided to adapt the old industrial school in Gem-street for the purposes of a special school for mentally defective children. At the last meeting of the Birmingham education committee Mrs.

Hume Pinsent, the chairman of the special schools subcommittee, was asked how parents received the decision that their children were mentally deficient and in the event of a parent not being satisfied whether there was, as it were, any court of appeal? In reply, Mrs. Pinsent stated that to the admission examination the parents were summoned, as well as the teacher of the child, His Majesty's inspector, the chairman of the education committee, and the medical man who was examining. In 99 cases out of 100 no objection whatever was made by the parents. They frequently had parents bringing children and asking that they should be admitted to the schools. It was further stated that the subcommittee was waiting for the report of the Royal Commission which was now sitting before bringing forward any scheme for permanent boarding schools for these children.

Dr. Duncan Forbes, who has been for some time assisting

the gift of the Crown on the recommendation of the Secretary for Scotland who, under the new Government, is the Right Hon. John Sinclair, M.P., a son-in-law of Lord Aberdeen.

The Morison Lectures in Edinburgh.

These lectures¹ were favoured by a good attendance, many men engaged in lunacy work having evidently come to Edinburgh to hear them. The lecturer was well heard, and his material was well arranged and fully illustrated by means of lantern slides and microscopic preparations.

The Teaching of Gynaecology in the University of Edinburgh.

It is understood that the University of Edinburgh has decided to separate the teaching of gynaecology from the Chair of Obstetrics. Meanwhile communications are taking place between the managers of the Royal Infirmary and the University with regard to the arrangements to be made in the infirmary. It is not proposed to appoint a professor of gynaecology but to make the new post a lectureship. It is understood that by the Ordinances of the Scottish Universities Edinburgh cannot make a new chair without the sanction of the other Scottish Universities, while there seems to be no such difficulty regarding the establishment of a lectureship. The teaching of gynaecology is necessarily a most difficult and delicate question in this country, particularly in general hospitals with many students. The difficulty is necessarily lessened the greater the number of teachers or of local institutions where limited numbers of students can receive practical instruction, but such arrangements would imply an amount of organisation and of decentralisation which does not come within the horizon of University policy.

The Customs of Hairdressers.

Even to the average layman with a weakness for cleanliness in all that relates to his own person, the customs of hairdressers sometimes give rise to a few qualms. In the case of the medical man educated to a firm belief in asepsis and with a clear knowledge of all the dangers lurking in a barber's "shave" or in the rotary brush it is matter for wonder that he ever has courage to set foot in a barber's shop. Glasgow has determined to remedy this state of affairs, not that she is worse in this respect than other cities, but an effort is to be made to bring the arrangements of all hairdressers' shops up to the standard which already exists in the better class shops of that kind. The health committee has had several meetings with representatives from the Hairdressers' Guild, as the result of which a series of regulations relating to cleanliness and prevention of infection has been adopted by the committee. In addition a register is to be kept by the medical officer of health of the names and addresses of all hairdressers in the city who comply with the regulations and recommendations and apply for registration. A certificate of registration will be issued by the corporation to each hairdresser so registered.

Wastage of Child Life.

A lecture on Wastage of Child Life was delivered in Edinburgh on Jan. 23rd under the auspices of the Parents' National Educational Union by Mr. Broadbent, mayor of Huddersfield. Professor C. Hunter Stewart presided over a large audience of ladies and gentlemen. Mr. Broadbent referred to the fact that the death-rate of children under one year of age was a clear index of the health conditions of the children who survived, and it was probable that for every infant life which might be saved at least six lives might be made better and healthier. Every life lost pointed to many lives injured, and he suggested that many of the unfit had been rendered unfit in the first place by the unfair treatment which they had received in their early infancy. The high death-rate was due not so much to a deficiency of vital force in the infants as to the conditions surrounding them, which made 95 out of 100 infants survive in one part of a town and only 60 out of 100 in another part. The causes which led to this waste of life were ignorance and indifference. Overcrowding, deficient milk-supply, and the employment of married women in factories were secondary influences. The mothers were not to blame. The fault was to be found in the indifference of statesmen and educationists. It was the fault of the so-called educated classes. They had had compulsory education in force nearly 35 years and the result was that the mothers of to-day were as a rule totally ignorant of the elementary duties of motherhood. They did not allow the future mothers to stay at home and

learn the elementary duties of motherhood. The girls were compelled to attend school and as soon as they were able they had to go to work. Often everything was done to prevent them having any intimation that motherhood was the highest privilege of their sex. His remedy was to help the mothers in their own homes to feed, tend, and care for their own babies. Mr. Broadbent then explained the system which had been established in Huddersfield. One shilling was given for the prompt notification of any birth and a notice of birth not thus notified was obtained from the registrar. Lady health visitors, appointed by the corporation, paid a visit to the home as soon after a birth as possible, leaving a card of advice and giving whatever good counsel was practicable. After the visit of the lady health visitor the health of the baby was looked after by a voluntary organisation which embraced the whole town in its operations. The work of this organisation consisted of systematic visiting entirely from the health point of view and not for the purpose of giving charity. The attempt was new but it was proving very satisfactory. Dr. T. S. Clouston, Dr. W. Leslie Mackenzie, Dr. Elsie M. Inglis, and others spoke and expressed their interest in the work and dwelt upon the importance of it.

Greenock Infirmary.

In consequence of complaints by ratepayers relating to the fever house of Greenock Infirmary an inquiry has been instituted by the Local Government Board. As regards the alleged difficulty of parents in getting information as to the progress of children who are inmates of the fever house, it has been arranged that all such inquiries are to be made at a certain hour every day instead of on only four days of the week. Another alleged grievance was insufficiency of accommodation in the fever house. Dr. F. Dittmar, however, who is investigating the matter on behalf of the Local Government Board, states that he visited all the wards in which patients, mostly children, were under treatment and found them clean, airy, and well kept. There could be no doubt, on the other hand, that the nurses were very poorly and unsatisfactorily housed and, strictly speaking, some of their rooms were uninhabitable. They were dingy, in some cases damp, and were situated in the basement of the fever house. In several of the rooms inspected by Dr. Dittmar the floors were under the level of the area outside.

The Care of the Insane.

The quarterly meeting of the Aberdeen, Kincardine, and Banff Association of Inspectors of Poor was held on Jan. 27th in the Music Hall Buildings, Aberdeen, at which a paper was read by Dr. Charles Macpherson, Edinburgh, Deputy Commissioner in Lunacy for Scotland, on the subject of "the family care of the insane, more particularly with reference to its present position and possibilities of development in Aberdeen, Kincardine, and Banff." Mr. John W. Gordon, Rathven, President of the society, occupied the chair, and there was a large attendance of members of the association and also of members of the parish councils in the three counties.

Jan. 30th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal College of Surgeons in Ireland.

THE annual dinner of the Royal College of Surgeons in Ireland has been announced to take place on Saturday, Feb. 17th. His Excellency the Lord Lieutenant has signified his intention of being present.

Coroners' Inquests in Railway Accident Cases.

A deputation from the Parliamentary Committee of the Irish Trades Congress waited on the Chief Secretary at Dublin Castle on Jan. 27th for the purpose of laying before him some grievances which in its opinion required the attention of the Government. Amongst other matters Mr. Walter Hudson, M.P., the recently elected member for Newcastle-on-Tyne, said that at coroners' inquests in railway accident cases technical experts should be allowed to appear on behalf of the next of kin. The Chief Secretary gave a favourable reply to the suggestion, stating that it rested with the discretion of the coroner but that he saw no reason why the latter should refuse.

Ulster Medical Society.

At the third meeting of the present winter session, held in the Belfast Medical Institute, on Jan. 25th, the President

¹ We publish an abstract of the first lecture on p. 324 of our present issue.—Ed. L.

infirmary the whole question of increasing the subscriptions has been intrusted to a committee whose efforts have already met with a considerable measure of success.

Jan. 30th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Opening of the Newport (Mon.) Borough Asylum.

THE joint lunatic asylum at Abergavenny was established in the year 1852 for the treatment of patients from the counties of Monmouth, Hereford, Brecon, Radnor, and the city of Hereford. In 1870 patients from the city and county of Hereford were removed to the asylum at Burghill, in Herefordshire, and in 1903 the Breconshire and Radnorshire patients were removed to the new asylum at Talgarth. The latest, and what will probably be the final, depletion has now been accomplished by the removal of the Newport borough patients to the new asylum which has been erected at Caerleon. Provision was made in 1852 for 210 patients at the Abergavenny institution, but subsequent enlargements in 1861, 1878, 1882, and 1892 increased the accommodation to over 1100 beds. In 1897 the county council of Monmouth, under the provisions of the Lunacy Acts, required the corporation of the borough of Newport to provide its own asylum accommodation and to remove its patients from Abergavenny, and in 1899 the corporation undertook to remove its patients optionally at the end of 1903 and absolutely at the end of 1906. This agreement will be carried out well within the stipulated time, for on Jan. 25th the mayor of Newport formally opened the Caerleon institution. The site is 126 acres in extent and commands extensive views of the surrounding country. There is at present accommodation for 368 patients, equally divided between the two sexes, but the administrative offices are designed for 500 patients. The main buildings include a central administrative block with three two-storey blocks on either side, all being connected by covered corridors. The blocks nearest to the administrative offices are for 60 sick and infirm cases in two wards; the next block is for 35 epileptics on the ground floor, and for 35 quiet chronic cases on the upper floor; while in the furthest blocks there is accommodation on each floor for 27 recent and acute cases. Classification is much facilitated by the adoption of these small wards and by each ward having its sleeping accommodation adapted to the class of patient resident in that ward, both as to the position of the dormitories and of the single rooms. The general planning has been very thoughtfully carried out, especially as regards the kitchens, central dining hall, stores, and laundry. The same care has not, however, been displayed in certain minor details and the number of exposed beams, architraves, and dust ledges generally are more than one would expect to find in a present-day institution intended for the reception of the sick. The buildings are lighted by electricity and heated by hot water on the "cable" system. The water-supply is from the corporation mains, storage tanks being provided to hold a day's supply. The total cost of the institution will approximate £400 per bed, a sum capable of reduction if the additional blocks are erected. The furnishing has been carried out at the low figure of £25 per bed. Dr. W. F. Nelis, who was assistant medical officer for 25 years at the Abergavenny Asylum, was some months ago appointed medical superintendent and he has been actively engaged in preparing the institution for the reception of the patients, many of whom are now being removed from Abergavenny.

Cardiff College.

In an address which Sir Arthur Rücker, F.R.S., recently delivered before the Association of Past Students of the University College of South Wales and Monmouthshire he urged that time and opportunity for research should be given to professors in every university and deprecated the idea of an artificial cleavage into the unity of knowledge by devoting too much attention to pure literature and science on the one hand and to technology on the other. In connexion with the provision of university teaching he expressed the opinion that the site, buildings, and initial equipment of university colleges must come from sources other than the fees of the students and stated that in Cardiff the whole of the capital and three-fourths of the general income were derived from

outside sources and that the students paid only about one-fourth of the cost of their education.

The Medical Officer to the Cardiff Education Committee.

The medical officer of health of Cardiff (Dr. E. Walford) was last year appointed medical officer to the education committee and it has been recently decided to pay him a salary of £1 per annum for each of the 37 schools in the city. In reply to an inquiry the Local Government Board has stated that a medical officer of health is entitled to extra remuneration for acting as medical officer to an education committee.

University of Wales.

At a meeting of the Court of the University of Wales held on Jan. 25th the Senior Deputy-Chancellor (Sir Isambard Owen) said that he hoped in the present year they would get through their supplemental charter and also be allowed to establish a faculty of medicine. The reputation of the University, he said, would depend to a large extent upon the faculty of medicine. It has been decided to ask the President of the General Medical Council and the President of the Royal College of Physicians of London to assist in the drafting of the Bill which will have to be presented to Parliament enabling the University to establish a faculty of medicine.

South Wales Water Board.

The Glamorganshire county council is pressing on the preparations for presenting in the next session of Parliament a Bill for the formation of a water board for South Wales. The Breconshire county council has decided to oppose the measure on the ground that it will interfere with its rights, some of which it is thought have not in the past been sufficiently safeguarded.

West Wales Sanatorium.

It was confidently expected that each of the three county councils of Pembrokeshire, Cardiganshire, and Carmarthenshire would vote a sum of at least £500 out of county funds towards the erection of the West Wales Sanatorium. The Carmarthenshire council had, indeed, already decided to give this sum, so that it was a distinct disappointment to those interested in the institution to learn that the Local Government Board has expressed the opinion that the council cannot legally hand over the money. The Board gave a contrary opinion with regard to district councils, several of which have paid capital sums towards the erection of sanatoriums.

Assault on a Medical Cyclist.

At the Bristol county-court, before his honour Judge Austin, Mr. F. C. Whitmore, M.R.O.S. Eng., brought an action against a cattle dealer for personal injuries sustained. Evidence showed that the defendant, who was intoxicated, was driving a vehicle on the wrong side of the road and knocked Mr. Whitmore off his bicycle, breaking the machine. When he was remonstrated with he struck the plaintiff across the neck with his whip. Mr. Whitmore was injured in the abdomen and unable to follow his professional duties for a week. The defendant was ordered to pay ten guineas and costs.

Winsley Sanatorium.

The Winsley Sanatorium has been open for the reception of patients for 12 months, during which time 143 patients have been admitted, the weekly cost of each being about 25s. Jan. 29th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Chair of Medical Jurisprudence in the University of Edinburgh.

OWING to the resignation of Sir Henry D. Littlejohn of the Professorship of Medical Jurisprudence in the University a vacancy has occurred somewhat unexpectedly. So far only two candidates are in the field, one of whom is Dr. H. Harvey Littlejohn, F.R.C.S. Edin., a son of Sir Henry Littlejohn, and who has been a lecturer on medical jurisprudence in the Extra-mural School of Edinburgh for several years, having previously spent some years in Sheffield as medical officer of health there. The other candidate is Dr. W. G. Aitchison Robertson, F.R.C.P. Edin., who has also lectured for a number of years in the Extra-mural School of Edinburgh on the same subject. The appointment is in

Kiel and Professor von Strümpel of Breslau have declined it as they could obtain no assurance of charges which they thought necessary.—*Würzburg*: Dr. Paul Roetter, *privat-docent* of Ophthalmology, has been promoted to an Extraordinary Professorship.

MEDICAL BARRISTERS.—The following medical men have been "called to the bar" this term: by Lincoln's Inn, Stanley Melville, M.D. Brax, M.R.C.S. Eng., L.R.C.P. Lond., of Kensington; by the Middle Temple, John Edward O'Connor, M.B. R.U.I., of Leicester, Albert Henry Bycott, M.D. Lond., of Birmingham, and Charles Porter, M.D., B.Sc. Edin., M.R.C.P. Edin., of Sheffield.

UNIVERSITY OF CAMBRIDGE.—The following have passed the examination in tropical medicine and hygiene and are entitled to the University diploma: James Booth-Clarkson, John Crichton Stuart McDonald, and Robert Small.—On Jan. 29th 32 additional freshmen were matriculated, bringing the total for the present academical year up to 1048.—The new regulations with regard to the admission of candidates for M.B. and M.D. who are resident abroad were approved by the Senate on Feb. 1st.—The following candidate was at the same congregation admitted by proxy to the degree of Doctor of Medicine: Owen Frank Paget, M.B., Gonville and Caius College.

PRESENTATION TO A MEDICAL PRACTITIONER.—The Hon. William Thomas Prout, C.M.G., M.B. C.M. Edin., principal medical officer in Sierra Leone, has been presented with an address, a pair of silver rose bowls, and a pair of silver flower vases by members of the West Africa Colonial medical staff to mark their appreciation of the honour which the King recently conferred upon Dr. Prout by making him a Companion of the Order of St. Michael and St. George. The address, which was signed by 13 medical men, referred to the good work which Dr. Prout has done in connexion with sanitary matters in the various stations of the Protectorate.

THE GLASGOW AND WEST OF SCOTLAND CO-OPERATION OF NURSES.—The Glasgow and West of Scotland Co-operation of Trained Nurses has just celebrated the thirteenth anniversary of its foundation and the report recently passed at the annual meeting shows that the institution is in a very flourishing condition indeed. The number of nurses on the roll is 181, the number of cases nursed during the past year is 1772, and the total earnings for the year amount to £10 533. It is a great satisfaction to find that affairs are in such a flourishing condition. The advantages of such an institution to the public, to the medical profession, and more especially to the nurses themselves, are very obvious, and the committee is to be congratulated on the steps that it is taking to establish sick and pension funds for the nurses.

LITERARY INTELLIGENCE.—The St. Bride's Press will publish on Feb. 19th a work on "Crematoria in Great Britain and Abroad," by Albert C. Freeman. The author, an architect who has made a close study of this subject, has collected a considerable amount of data and he gives 70 practical illustrations of crematoria, columbaria, and cremating furnaces in use in all parts of the world.—Mr. H. J. Glaisher has just ready Mr. A. de Prenderville's new book entitled "Anesthetic Technique for Operations on the Nose and Throat."—Messrs. J. and A. Churchill have nearly ready for publication a book entitled "Clinical Applied Anatomy, or the Anatomy of Medicine and Surgery," by Dr. C. R. Box, physician for out-patients and lecturer on applied anatomy, St. Thomas's Hospital, and Mr. W. McAdam Eccles, assistant surgeon and lecturer on surgical anatomy, St. Bartholomew's Hospital. This work describes how the facts of anatomy influence the incidence and progress of disease and injury. No attempt is made to discuss the details of anatomy in a systematic manner, but the various lesions are reviewed and the anatomical points bearing upon them are indicated. Many of the plates are original and coloured and serve to illustrate relationships of great importance.—Mr. Henry Forde is about to bring out a book written by Dr. F. J. Stearns, the medical officer of health of Camberwell, on the subject of the dissemination and prevention of small-pox. It deals, among other things, with the spread of the disease from hospitals and the ordinary and extraordinary means of conveying the infection from one person to another and discusses the value of measures designed to prevent its spread both from a medical and a financial point of view.

THE GENERAL ELECTION.—The following members of the medical profession have been returned to Parliament: Mr. R. Ambrose, L.R.C.P., L.R.C.S. Edin., re-elected for West Mayo; Sir William J. Collins, M.D. Lond., F.R.C.S. Eng., late chairman of the London County Council, elected for St. Pancras (West); Mr. G. J. Cooper, M.B.C.S. Eng., L.S.A., elected for the Bermondsey division of Southwark; Sir B. Walter Foster, D.C.L., LL.D., M.D. Erlang., F.R.C.P. Lond., re-elected for the Merton Division of Derbyshire; Mr. F. Rutherford Harris, L.R.C.S. Edin., re-elected for the Dulwich division of Camberwell; Mr. G. H. Pollard, M.D. Edin., elected for the Eccles division of Lancashire; Mr. R. J. Price, M.R.C.S. Eng., re-elected for East Norfolk; Mr. A. R. Raby, M.B., C.M. Edin., elected for the Kilmarnock Burghs; Sir G. S. Robertson, K.C.S.I., M.R.C.S. Eng., L.S.A., I.M.S. (retired), elected for Bradford (Central), and Mr. V. H. Rutherford, M.B. Cantab., &c., elected for the Brentford Division of Middlesex. Amongst those who have lost their seats are Sir Michael Foster, K.C.B., M.B. Lond., and Mr. C. F. Hutchinson, M.D. Edin. The results of the polling for the representation of the Universities of Edinburgh and St. Andrews and the Universities of Glasgow and Aberdeen, for which constituencies Sir John Barry Take, M.D., and Professor W. R. Smith, M.D., are respectively candidates, we shall announce next week.

'APOTHECARIES' HALL OF IRELAND.—The following were the results of examinations held in January: W. Shaw-Stewart passed in chemistry and junior anatomy, completing the first professional examination; J. E. McDonogh in chemistry and physics; M. Moody in senior anatomy, completing the second professional examination; J. Gillespie in all subjects, D. J. Boyle and J. Hartigan in pharmacy, and N. J. Murphy in hygiene, all completing the third professional examination; M. Moody in hygiene; J. Gillespie and J. Hartigan in medicine, surgery, midwifery, and ophthalmology, completing the fourth (final) professional examination; and D. J. Boyle in medicine, surgery and midwifery. The diploma entitling the holder to practise medicine, surgery, midwifery, and pharmacy was granted to J. Gillespie and J. Hartigan.

DONATIONS AND BEQUESTS.—An endowment fund of £10,000, producing nearly £300 a year, has been handed over to the Frank James Memorial Hospital at Cowes, of which Princess Henry of Battenberg is the president, by Messrs. James, who gave the hospital.—Under the will of Mr. James Henry Ceely, F.R.C.S. Eng., £500 are bequeathed to Epsom College.—A donation of £100 has been received by the Paddington Green Children's Hospital from a friend who wishes to be known as "Marnie."—The late Mr. Alexander Laing, who died on Oct. 11th, 1905, at Newcastle-upon-Tyne, besides his very generous gift to the city of the art gallery which bears his name, by his will bequeathed £1000 to the Royal Infirmary; £200 each to the Newcastle Dispensary, the Royal Victoria Asylum for the Blind, the Northern Counties Orphanage, the Northern Counties Institution for the Deaf and Dumb, the Fleming Memorial Hospital for Sick Children, the Hospital for Incurables, the Tyne-mouth Victoria Jubilee Infirmary, North Shields, and the Prudhoe Memorial Convalescent Home, Whitley; also £100 each to the Throat and Ear Hospital, the Eye Infirmary, and the Dental Hospital, all of Newcastle-upon-Tyne.

THE BOHEMIAN TWINS.—In many lay papers there has appeared a notice that the "Bohemian Twins," Misses Rosa and Josepha Blazek, who have been seen in exhibitions in this country, have been separated by an operation at a university in Prague. We have had forwarded to us an interesting letter received from Professor Dr. V. Kukula of Prague correcting the mis-statement. "I have removed," he writes, "from the twins, Misses Rosa and Josepha Blazek, or rather from Miss Rosa, a vesical calculus about the size of a large hen's egg by lithotomy. This operation was performed under great difficulties. Firstly, it was impossible to put the twins in a suitable position to enable me to operate. Secondly, the bladder did not permit of being filled with liquid; it therefore made it more difficult to manipulate with instruments. The operation was performed with the assistance of chloroform and though Rosa had great pain Josepha felt no pain at all. The sisters have only one urethra up to the point where it divides to enter the two thoroughly distinct bladders.

(Dr. W. Calwell) being in the chair, Dr. R. W. Leslie read notes of a case of Pernicious Anæmia treated by Cacodylate of Soda.—Mr. A. B. Mitchell gave an account of a case of Complete Excision of the Scapula and showed a patient in whom enterectomy and gastro jejunostomy were performed at the same sitting; he also showed an Emphysematous Tumour of the Intestine removed from the patient previously exhibited, as well as a cystic kidney successfully removed for hæmaturia and a fibro-cystic tumour of the breast.—Dr. A. Gardner Robb read a note on two unusual cases of Perforation in Typhoid Fever.—Mr. Robert Campbell gave an account of a case in which for chronic Bright's disease he had decapsulated the kidneys (Edebohl's operation).

Belfast Hospital for Sick Children.

At the thirty-third annual meeting of the supporters of this hospital, held on Jan. 25th (the Hon. R. T. O'Neill, M.P., in the chair), it was reported that there were 843 intern cases treated in the wards (427 medical, 401 surgical, and 13 ophthalmic). 365 operations were performed. In the extern department 5196 cases were treated, and of these 2802 were medical, 1562 surgical, 608 dental, and 224 eye and ear cases. In this department 341 operations were performed. Financially, the total income was £1670, as compared with £1447 in the previous year. The cash balance, £368, was less than last year, when it was £800. The total expenditure was £2149, as compared with £2210 last year, and the amount of invested funds was £9817. In the remarks of the various speakers reference was made to the high death-rate among infants in Belfast (146 per 1000) which arose from preventable causes, such as carelessness, insufficient nourishment, and generally from improper feeding. Attention was called to the efforts made by the hospital authorities to prevent this mortality by distributing pamphlets giving directions to mothers relating to the care and feeding of infants. Some of the speakers also suggested that the Hospital Saturday and Sunday collections should be for all the hospitals of the city and they thought that in this way more money would be raised.

Belfast Union Infirmary.

Mr. Joseph Fulton, L.R.C.P. & S. Edin., has been appointed by the Belfast board of guardians visiting surgeon to the Belfast union infirmary in the place of the late Dr James Lyness.

Jan. 30th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The X Rays and Medical Practice.

Two recent sessions of the Academy of Medicine—namely, those held on Jan. 9th and 16th—have been devoted to the consideration of this important subject. M. Chaffard, who opened the discussion with a paper which was listened to with rapt attention by the Academy, read in the course of it a report drawn up by him on behalf of a commission which had been appointed to consider the legal conditions of the employment of the x rays for medical purposes. Eight months previously M. Debove drew attention to the many and various dangers to which the use of the x rays on man gave rise in the hands of those who were not legally authorised to practise medicine. At the same date a congress sitting in Berlin had come to the unanimous conclusion that the use of the x rays on man was strictly the province of the medical profession. M. Chaffard pointed out that these rays since their discovery some ten years ago had been made the subject of numerous investigations which had shown that their action was attended by unexpected and powerful results which it was not possible to consider as matters simply of scientific curiosity and that they could not be used by the first comer without any risk. As a matter of fact, the use of these rays had brought about severe and incurable burns of the skin and glandular atrophy of a startling character in persons who were in the habit of working with them. Finally, in many patients treated by these rays for cancer of the tongue the growth had become rapidly disseminated. M. Chaffard maintained that it was a logical deduction to state that only a qualified medical man should use these rays and even ordinary cases of diagnosis by the rays, such as that of a fracture, needed a medical man rightly to interpret the results arrived at. At present any person can use the rays and it is quite time that

the authorities should intervene in the interests of the public. Even in cases of simple radiography some surveillance should be exercised, for radiographs could be easily "faked" and give rise to all sorts of errors. M. Chaffard concluded by asking the Academy to declare that the medical application of the x rays by persons who were not doctors of medicine, *officiers de santé*, or duly qualified dentists, should constitute an act of illegal practice. M. Reynier declared that it was not possible to assign all the evil results which had followed the use of the x rays to the want of a diploma in those who used them. Many physicians had to deplore unfortunate results from their employment. For the right use of the x rays it was not enough that a man should be a medical practitioner, he must also have some technical knowledge. A physicist in his opinion could handle the rays better than a medical man. M. Chaffard replied that physicists had had just as bad accidents with the rays as medical men, but they did not use them for medical purposes. M. Cornil discussed the pathological conditions in which the x rays had proved useful or the reverse. In cancer of the mucous orifices or of the tongue they were harmful. M. Reynier said that accidents could be avoided by means of a sound technique and that all medical men should be instructed in such so as to avoid the dangers mentioned. Till then let all x ray treatment be ordered by a medical man but not necessarily applied by a medical man. M. Gariel remarked that it was easier for a medical man to learn physics than for a physicist to learn medicine. M. Brouardel said that great danger arose from the unrestricted use of the x rays. M. Debove said that the persons who treated people with the x rays, other than medical men, were a most motley crowd and the abuse should no longer be tolerated. Treatment by the x rays should be solely in the hands of medical men. Moreover, as a matter of fact, the technique is taught in the course of medical physics at the faculty. M. Labbé and M. le Denla both protested against the argument founded upon the fact of accidents occurring in the hands of medical men using the rays. The most skilled anaesthetists occasionally had disasters with chloroform. Finally, the Academy unanimously adopted M. Chaffard's conclusions and in future medical men alone will have the right to use the x rays for treatment.

Jan. 30th.

Medical News.

FOREIGN UNIVERSITY INTELLIGENCE—*Berlin:*

Dr. René du Bois-Reymond of the Physiological Institute has been granted the title of Professor and Dr. Otto Schjerning, Surgeon-General in the German Army, has been appointed an Honorary Professor in the Medical Faculty of the University.—*Breslau:* Dr. Hermann Triesep of Graefswald has been offered the appointment of Senior Professor in the Anatomical Institute in succession to the late Dr. A. Schaper.—*Erlangen:* Dr. Wolfgang Weichardt has been recognised as *privat-docent* of Experimental Therapeutics.—*Göttingen:* Dr. Jesionek of Munich has been appointed Extraordinary Professor of Dermatology.—*Jena:* Dr. Jean Noll, *privat-docent* of Physiology, Dr. Julius Grober, Assistant in the Medical Clinic, and Dr. Hans Berger, Resident Physician to the University Lunatic Asylum, have been promoted to Extraordinary Professorships.—*Königsberg:* Dr. Richard Ronge, Senior Surgeon in the University Clinic, has been granted the rank of Professor.—*Lemberg:* Dr. Josef Wiczkowski, *privat-docent* of Medicine, has been promoted to an Extraordinary Professorship.—*Leyden:* Dr. J. Brönlings has been recognised as *privat-docent* of Clinical Diagnosis.—*Louvain:* Dr. Schokaert has been appointed Professor of Midwifery.—*Munich:* Dr. Neumayer has been appointed Extraordinary Professor of Laryngology.—*Naples:* Dr. Pasquale Mazzeo has been recognised as *privat-docent* of Children's Diseases. Dr. Vincenzo D'Amato has been recognised as *privat-docent* of Dermatology.—*Paris:* Dr. Romolo Costa has been recognised as *privat-docent* of Midwifery and Gynecology.—*Prague (Bohemian University):* Dr. O. Völker has been recognised as *privat-docent* of Anatomy.—*Tübingen:* Dr. Kurt Wolf of Dresden has been appointed Professor of Hygiene.—*Vienna:* Dr. J. Donath has been recognised as *privat-docent* of Medicine. There has been some difficulty in filling the late Professor Nothnagel's chair of Medicine. Both Professor Quincke of

- Bristol Royal Infirmary.**—Obstetric Officer, Junior House Surgeon, and Casualty Officer. Salary of former £75 per annum and of two latter £50 each per annum, with board, lodging, and laundry in each case. Also *Honorary Physician and Honorary Surgeon*.
- Cancer Hospital,** Fulham road, London, S.W.—Senior House Surgeon for six months. Salary £20 per annum, with board and residence.
- Canterbury, Kent and Canterbury Hospital.**—House Physician, also House Surgeon, both unmarried. Salary in each case £50 a year, with board and lodging.
- Central Midwifery Board.**—Examiners.
- Cheltenham General Hospital.**—Surgeon-in Charge of Branch Dispensary, unmarried. Salary £50 per annum, with board and lodging. Also Junior House Surgeon, unmarried. Salary £20 per annum, with board and lodging.
- City of London Hospital for Diseases of the Chest,** Victoria Park, E.—Two Physicians to Out patients.
- Dublin, Richmond District Asylum.**—Two Clinical Assistants. Salary £50 per annum, with apartments and rations.
- Dorset County Council.**—Inspector of Midwives and Health Visitor (female). Salary £120 per annum, rising to £150, with travelling expenses.
- Guildford, Royal Surrey County Hospital.**—Assistant House Surgeon. Salary £50, with board, residence, and laundry.
- Hospital for Sick Children,** Great Ormond street, London, W.C.—Assistant Casualty Medical Officer, unmarried, for six months. Salary £20, with board and residence. Also House Physician, unmarried, for six months. Salary £20, with board and residence. Also Assistant Surgeon.
- Larbert, Stirling District Asylum.**—Assistant Medical Officer. Salary £150, with board.
- Leeds General Infirmary.**—Resident Medical Officer. Salary £100 per annum, with board, residence, and washing. Also Clinical Pathologist. Salary £20 per annum.
- Leicester Infirmary.**—Assistant House Physician for six months. Salary at rate of £50 per annum, with board, lodging, and washing.
- Midwifery Council.**—Medical Officer to Employes in the Boroughs of Hammermith and Fulham.
- Nottingham County Hospital.**—Senior House Surgeon, unmarried. Salary £100 per annum, with board, lodging, and washing.
- Nottingham, Asbestos Hospital.**—Resident House Surgeon. Also Resident House Physician. Salary of former £100 and of latter £20 per annum, with board, residence, &c., in each case.
- Nottingham Hospital for Consumption and Diseases of the Throat and Chest.**—Honorary Surgeon.
- Argate, Royal Sea Bathing Hospital.**—Resident Surgeon. Salary at rate of £50 and £120 per annum, with board and residence.
- St. Metropolitan Hospital,** Kingsland-road, N.E.—Assistant Physician.
- St. Mary and St. George's.**—Medical Officer of Health. Salary £50 per annum.
- Newcastle-on-Tyne Dispensary.**—Two Visiting Medical Assistants. Salary £100, rising to £120 per annum.
- St. Peter, Radcliffe Infirmary.**—House Physician and Junior House Surgeon (both unmarried) for six months. Salaries at rate of £20 and £40 per annum, with board, &c.
- Total Free Hospital,** Gray's Inn road, W.C.—Anaesthetist and Curator of Museum (female).

Mr. Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Ashton-under-Lyne, in the county of Lancaster; at Belfast, in the counties of Antrim and Down; at Dunkinfield, in the county of Chester; at Tatum, in the county of Galway; at Fording, in the county of Mayo; and at Oxford, in the county of Oxford.

Births, Marriages, and Deaths.

BIRTHS.

- FRASER.**—On Jan. 22th, at Ingleisle, Lower Edmonton, N., the wife of Simon Fraser, M.B., of a daughter.
- HERBERT.**—On Jan. 22th, at Carrington House, Pendlebury, Manchester, the wife of J. W. Chambers Herbert, Surgeon, of a daughter.
- WAGSTAFF.**—On Jan. 25th, at Saffron Walden, Essex, the wife of Frank A. Wagstaff, M.R.C.S., L.R.C.P., of a daughter.

DEATHS.

- FOTHERGILL.**—Smart Atkinson Fothergill, M.R.C.S., L.R.C.P. Edin., 65 years, Sunderland, co. Durham, died on 23rd January, 1906, aged 65 years.
- REBEARD.**—On Jan. 22th, at Grindelwald, Switzerland, of pneumonia, Henry William Rebeard, Lieutenant-Colonel, R.A.M.C., in his 50th year.
- LEIGHARD.**—On Jan. 21st, at Kirkby Lonsdale, William Edward Leighard, L.R.C.P. Edin., M.R.C.S. Eng., aged 59 years.
- PAINE.**—On Saturday, Jan. 6th, at Bournemouth, George Reuben Paine, M.R.C.S., L.R.C.P., late of Lymington, Devon. Laid to rest in Fordingbridge Cemetery.
- WELLS.**—On the 22th of Jan., at his residence, Russell Lodge, 15, Heathfield road, S. Croydon, George Wells, M.R.C.S. Eng., L.S.A., late of Wandsworth, aged 65.

N.B.—A fee of 6s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE AMERICAN QUACK.

A CORRESPONDENT who writes from Newcastle-on-Tyne and who is not a medical man but a layman reads us cuttings from the *Evening Chronicle*, a Newcastle paper, of Jan. 22nd, from the *Newcastle Daily Chronicle* of Jan. 16th, and also a publication called "The American X Ray Messenger," which is undated, but is stated to be published by the English branch of the American Institute, Fernwood-road, Newcastle-on-Tyne. This latter publication is simply and solely devoted to trumpeting the talents of an American called C. J. Macaura who is stated to be a graduate of the National Medical University of Chicago. This institution which, according to the *Newcastle Daily Chronicle*, is the "leading medical school in Chicago" (we wonder what the Rush Medical College will say to this), is a homeopathic establishment and was, according to the Standard Medical Directory of North America for 1903-04, organised in 1891, but in the list of American physicians published in the same directory we are unable to find Dr. Macaura's name. It is quite obvious from the "American X Ray Messenger" that he is a man of the regular type of American quack. There are testimonials purporting to come from various Nonconformist ministers, lady journalists, and a dentist called "J. James, M.D., D.D.S., F.R.S.L.," who, however, appears in the Dentists' Register as being qualified to practise because he was in practice before 1878, and there is also a testimonial from "a well known Bradford physician," signed "J. Bradley, L.R.C.P., L.F.P.S.G., 2, Band-street, Bradford." If Mr. Bradley really did give this testimonial it appears to us that the General Medical Council should take some notice thereof. Newcastle-on-Tyne has just returned two Labour Members to Parliament and it is astonishing that such a hard-headed community should, if we may trust what appear to be editorial paragraphs in the Newcastle papers which we have mentioned, be so easily duped.

THE SALARIES OF POOR-LAW MEDICAL OFFICERS.

To the Editors of THE LANCET.

SIRS,—Now that the Poor-law Commission is sitting I wonder if the salaries and fees paid to Poor-law medical officers will come under review. The present scale must, I think, be admitted as most inadequate for the services rendered by the members of a learned profession. Is the paucity of medical men in Parliament partly responsible for this? and is the far larger number of members of the legal profession in the House of Commons the reason of legal appointments being as a rule so much better paid? It would be interesting to compare the duties, responsibilities, and emoluments of, say, a revising barrister and of a parish medical officer. Perhaps someone acquainted with the work of both appointments would do this for us? If we complain of our poor reward we are soon told that there are plenty of other men who would be glad of the post. But this, I maintain, does not meet the case at all and is a quite unworthy argument. If the position of a revising barrister was advertised for competition at half the salary now paid the number of candidates would, I am convinced, excite some comment. I am, Sirs, yours faithfully,
Jan. 30th, 1906. M.O.

CONCERNING TUCKER: A WARNING.

THE man Tucker, whose real name appears to be John Dale Tucker, concerning whom we published a paragraph in THE LANCET of Jan. 27th, was on Jan. 25th charged on a warrant issued by the Director of Public Prosecutions at the Southam Petty Sessions, the charge being one of feloniously giving a false certificate relating to the death of Mary Lyne. The prisoner was remanded until Jan. 31st, bail being refused.

WANTED—A HOME.

THE daughter of a medical man in straitened circumstances has been recommended a short course of the "Wells-Mitchell" treatment. Her relatives can pay one guinea a week for six or eight weeks and her father would be very glad to learn of any institution where the assistance required could be obtained. We will forward any communications that we may receive.

THE REGISTRATION OF BIRTHS.

THE Kensington borough council is circulating the municipal bodies throughout England and Wales asking cooperation in approaching the Local Government Board with the object of urging that department to promote legislation for reducing the time allowed for the registration of births from 32 days to 21 days, as in Scotland. Under the present system particulars of the registration of children who die within the first month of life only reach the medical officer of health at about the same time as the registration of the child's death, and the motive of the Kensington borough council in taking the action above referred to is that if the period for registration were reduced the notification of the birth would be received in time to allow of such advice being given to the mother as might in some cases result in the saving of the infant's life.

I agree thoroughly with my English colleagues that an operation to separate the twins is impossible because of the nature of the connecting growth. In the case of one of them dying a separation would at once be necessary, but the success would be very doubtful. I very much regret that although the newspapers of Prague gave a correct report of what had been done nearly all foreign papers state that I have been successful in separating the two bodies. I take this opportunity to ask you to have the matter put in a right light in the English papers."

UNIVERSITY OF OXFORD.—The Vice-Chancellor has appointed the Right Hon Lord Curzon of Kedleston, M.A., Hon. D.C.L., All Souls' College, to be Romanes Lecturer for 1906—Scholarships in Natural Science are announced for competition as follows: On March 13th, Keble College; and on April 24th, Merton College, New College, and Corpus Christi College.—An examination for a Fellowship of the annual value of £200, tenable for three years, will be held in the present term. The examination will commence on Tuesday, Feb 27th. Intending candidates should send their names, addresses, and qualifications to the Regius Professor of Medicine, University Museum, on or before Saturday, Feb 10th. Further particulars will be found in the *University Gazette* of Jan 23rd (Clarendon Press).

DEATH OF A CENTENARIAN.—The death is announced, at Corfe, near Taunton, on Jan. 25th, of Mrs. B. Warren, at the age of 106 years.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions and others possessing information suitable for this column are invited to forward to THE LANCET Office, directed to the Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

BACKHOUSE, JOHN BURDER, M.B., Ch. M. Melb., has been appointed Public Vaccinator for the South Western District, Victoria, Australia.

BILL, GEORGE, M.B., Ch. M. Edin., has been appointed Public Vaccinator for the North Eastern District, Victoria, Australia.

BROWN, W. LANGDOY, M.D. Cantab., M.R.C.P., has been appointed Physician to the Metropolitan Hospital.

DICKMAN, H. G., M.B., M.S. Edin., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Holbeck District of the county of Lincoln.

FAIRFAX, N. P., L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Innerleithen District of the county of Peebles.

GRAHAM, J., L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Cockermouth District of the county of Cumberland.

GRANT, J. DUNN, M.D. Edin., F.R.O.S. Eng., has been appointed Honorary Aural Surgeon to the Royal Caledonian Asylum, Buxley Herts.

HALL, J. WALKER, M.D., Ch. B. Vict., has been appointed to the newly formed post of Pathologist, Bacteriologist, and Director of Clinical Laboratories at the Bristol Royal Infirmary.

HAYES, HORACE FREDERICK, M.B., Ch. B. Melb., has been appointed Public Vaccinator for the South Eastern District, Victoria, Australia.

IVENS, FRANCES, M.B., M.S. Lond., has been appointed Surgical Registrar to the Royal Free Hospital, Gray's Inn road.

LEMIX, OSCAR E., L.S.A. Lond., has been appointed Clinical Assistant to the Chelsea Hospital for Women.

MACFARLANE, W. D., M.B., M.S. Glasg., has been appointed Clinical Assistant to the Chelsea Hospital for Women.

MERRILEES JAMES FREDERICK, M.B., Ch. B. Melb., has been appointed Medical Officer of Health for the Shire of Kerang (Kerang District), Victoria, Australia, and Public Vaccinator for the North Western District.

REID, J. M.B., M.S. Aberd., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Doune District of the county of Perth.

ROCKETT, R. N. F., M.B. Melb., has been appointed Acting District Medical Officer and Acting Public Vaccinator pro tem. for Northam, West Australia.

SAUNDERS, J. H., M.B., Ch. B. Melb., has been appointed Acting District Medical Officer and Public Vaccinator for Broome and Quarantine Officer for the Port of Broome, West Australia.

SINCLAIR, THOMAS WALKER, M.B., Ch. B. Melb., has been appointed Assistant Medical Officer of Health for the Metropolitan Combined Districts, Department of Public Health, New South Wales, Australia.

TURNER, A. S., M.R.C.S. L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Beckenham District of the county of Kent.

WAUGH, ALEXANDER, L.R.C.P. Lond., M.R.O.S., has been appointed Deputy Medical Officer for the Midsummer Norton District of the Clutton Union.

WORGER, RICHARD GEORGE, L.R.C.P. Lond., M.R.C.S. L.S.A., has been appointed Deputy Medical Officer for the Radstock District of the Clutton Union.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BRADFORD POOR LAW HOSPITAL AND WORKHOUSE.—Resident Assistant Medical Officer, unmarried. Salary £100, with rations, apartments, and washing.

complicated by Pregnancy.—Dr. H. Macnaughton-Jones: A Note on Crysta of the Vagina. Paper.—Dr. Jelliff: Notes on Two Rare Conditions met with in the Pelvis during Operation. The President; Inaugural Address.

CHILDREN OF SOCIETY AND THE PAEDIATRIC CHILD STUDY ASSOCIATION (Parkes Museum, Margaret-street, W.).—8 P.M. Lecture.—Mr. J. C. Hudson: American Schools and their Relation to the Child and to Society. (Arranged by the British Child Study Association.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Abraham: Cases of Skin Disease.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury, W.C.).—3.30 P.M. Clinical Lecture.—Dr. J. Taylor: Syphilis of Nervous System.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. II. of 1905, which was completed with the issue of Dec. 30th, were given in THE LANCET of Jan. 6th, 1906.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1905 are now ready. Bound in cloth, gilt lettered, price 12s., carriage extra.

Cases for binding the half year's numbers are also ready. Cloth, gilt lettered, price 2s., by post 2s. 3d.

To be obtained on application to the Manager, accompanied by remittance.

THE LANCET AT THE RAILWAY BOOKSTALLS.

READERS who usually obtain their copies of THE LANCET at the bookstalls on the Great Western, the London and North Western, and the minor systems in connexion with these railways, are requested to communicate with the Manager, 423, Strand, London, W.C., if they experience any difficulty in getting copies of THE LANCET at these bookstalls, Messrs. W. H. Smith and Son's connexion with them having now terminated.

TO SUBSCRIBERS.

Will Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.				TO THE COLONIES AND ABROAD.			
One Year	...	...	£1 12 6	One Year	...	...	£1 15 8
Six Months	...	...	0 16 3	Six Months	...	...	0 17 4
Three Months	...	...	0 8 2	Three Months	...	...	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "To the Editors," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification.

METEOROLOGICAL READINGS.

AN ORIENTAL REMEDY FOR DOG BITES.

A CORRESPONDENT in the Indian Medical Service forwards to us the following prescription and letter of warning which were given to him by a Babu:—

Medicine for dog bite, known to me, by which I have cured many.

1. Rubbing *Kuchla* (fruit *Strychnia*) with a very small quantity of water (say five or six drops) and applying that paste to the wounded part daily once.

2. Taking only two hairs from another dog—i.e., not the dog that has bitten—putting them in a piece of plantain, and swallowing up that piece with two hairs within. On any Sunday.

At Oral, one dog suffering from hydrophobia bates six or seven; all died except the man who made use of the medicine—from me.

1.10.05.

N. K.

SIR,—I forgot to note down with reference to *Kuchla* (fruit *Strychnia*) that it is poisonous—especially for the dogs. It should be carefully rubbed; and the thing on which it is rubbed should be instantly washed, so that no dog may take the smell, or lick over the rubbed part. In short, *Kuchla* is poisonous, poisonous. Kindly note.

I am, Sir, your M.O. servt.,

N. K.

Kuchla is the *strychnos nux vomica*, of which the fruit has been said to be non-poisonous, but according to "The National Standard Dispensatory, 1905" (Churchill), the pulp contains strychnine. It is interesting to note in the second part of the prescription that the hair is not to be "a hair of the dog that bit you," but that of another dog, contrary to the usual proverb.

THE USE OF PARAFFIN IN NASAL DEFORMITIES.

To the Editors of THE LANCET.

SIRS,—Could any of your readers tell me whether time has shown that the advantage of this method of treatment is likely to be permanent? In suitable cases is there any risk of such subsequent ocular and intraorbital lesions as are reported in THE LANCET of Oct. 7th last to have come under the observation of M. Rohmer of Nancy? After the injection of paraffin is the colour of the skin of the nose uniform?

I am, Sirs, yours faithfully,

A. B. O

Jan. 30th, 1906.

SUPERCILIARY GYMNASTICS.

To the Editors of THE LANCET.

SIRS,—In reference to the paragraph headed "Superciliary Gymnastics," I may say that I have been able to do the same thing since I was 12 years old and I am now 37. I can also move any ear and keep the other still, or both at one time; also move the nostrils.

I am, Sirs, yours faithfully,

Dundee, Jan. 30th, 1906.

JAMES S. DOIG.

To the Editors of THE LANCET

SIRS,—On the subject of gymnastic eyebrows, I should like to inform you that I am able to raise one and lower the other eyebrow simultaneously and alternately as mentioned in the paragraph named and should be pleased to give any further information you may require.

I am, Sirs, yours faithfully,

Jan. 26th, 1906.

ERNEST J. BELL.

THE DENTAL SALIVA EJECTOR IN GENERAL SURGERY.

To the Editors of THE LANCET.

SIRS,—I was interested to read in THE LANCET of Jan. 20th, p. 162, that Dr. R. H. Woods of Dublin had used the dental saliva ejector in laryngeal operations. During the past year I have used it in intra-oral operations on several occasions and can corroborate Dr. Woods's favourable report as to its utility. I hope to see it before long used more generally by surgeons.—I am, Sirs, yours faithfully,

A. L. FLEMING,

Jan. 30th, 1906.

Anæsthetist, Bristol Royal Infirmary.

E. K.—We are obliged for our correspondent's kindly worded criticism, although the particular illustration referred to does not appear to be of a belt intended for the purpose suggested; still we are alive to the possibilities of mistake in this direction and will keep the subject in mind.

ERRATUM.—In the review of a book entitled "Cattle Tuberculosis" which appeared on p. 235 of THE LANCET of Jan. 27th the price was given as 2s. The price should have been 3s.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received:—St. Louis Medical Review, Notts Guardian, Dublin Express, Daily Chronicle, Dublin Times, Birmingham Post, Surrey Advertiser, Freeman's Journal, The Scotsman, Evening News, Liverpool Mercury and Journal, Daily News, Star, Westminster Gazette, American Medicine, Sheffield Independent, Northampton Daily Reporter, Bristol News, Newcastle Mail, Darlington Times, &c.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

A Series of Lectures

ON

APHASIA.

Delivered before the Royal College of Physicians of
EdinburghBy BYROM BRAMWELL, M.D. EDIN., F.R.C.P.
EDIN., F.R.S. EDIN.,PHYSICIAN TO THE EDINBURGH ROYAL INFIRMARY; LECTURER ON
CLINICAL MEDICINE IN THE SCHOOL OF THE ROYAL
COLLEGE, EDINBURGH, 17C.LECTURE II.¹THE CONSTRUCTION AND FUNCTION OF THE AUDITORY
SPEECH MECHANISM.

MR. PRESIDENT AND FELLOWS.—In order that the clinical features of auditory aphasia (word deafness) and of its different varieties may be clearly understood it is essential to come to a conclusion, so far as our present knowledge will enable us to do so, with regard to: (1) the position of the auditory centre in the cerebral cortex; (2) the course which the nervous impulses concerned in the hearing of speech sounds take in their passage from the ear to the auditory speech centre; (3) the function of the auditory speech centre; and (4) the manner in which auditory speech symbols (spoken words) are brought into relationship with the associated ("ideational") centres and so with the processes of thought. No one of these points can be said to be definitely settled. Leading authorities on aphasia hold different opinions with regard to each and every one of them.

THE POSITION OF THE CORTICAL CENTRE FOR HEARING.

The sound vibrations which constitute spoken words after entering the ear and being received on the end-organs of hearing stimulate (give rise to) nervous impulses which are conveyed by the auditory nerve and its upward prolongations to the auditory centre in the cerebral cortex.

Experimenters are not agreed as to the position of the auditory centre in the lower animals. Ferrier places it in the upper temporo-sphenoidal convolution. He found that in monkeys "electrical stimulation of the first temporo-sphenoidal convolution was attended with pricking of the opposite ear, wider opening of the eyes, dilatation of the pupil, and turning of the head and eyes to the opposite side—just the phenomena which occur when a loud noise is made in immediate proximity to the ear;" and that destruction of the upper temporo-sphenoidal convolution was followed by permanent deafness in the opposite ear. Bohlfers and Sanger Brown found that in monkeys complete destruction of the upper temporo-sphenoidal convolution—indeed of the whole of both temporo-sphenoidal lobes—did not produce total deafness. A. W. Campbell suggests as a probable explanation of these different results that Schüller and Sanger Brown failed completely to remove and destroy the transverse temporal gyrus of Heschl, which he (Campbell) thinks constitute the area of cortex in which simple auditory stimuli are (mainly) received. In man the auditory centre seems undoubtedly to be located in the upper part of the temporo-sphenoidal lobe. The general view is that the auditory centre is situated in the first or upper temporo-sphenoidal convolution. It would also appear that the posterior part (half or two-thirds) of the second temporo-sphenoidal convolution forms part of the auditory speech centre. Further, clinicopathological observations in man seem to suggest that in the cortical centre for hearing (the auditory centre as a whole) there are separate nervous mechanisms for the registration of: (a) ordinary sounds; (b) musical sounds; and (c) speech sounds.

If it be granted that the auditory centres for ordinary sounds, for musical sounds and for speech sounds, are all situated in, and confined to, the first or upper temporo-sphenoidal convolution, Professor Edgri's case of tone deafness (to which I will refer in detail in the next lecture)

would seem to show:² 1. That the anterior part of the auditory centre (first temporo-sphenoidal convolution) in both hemispheres of the brain is perhaps the part (or the chief part) of the (main) auditory centre in which ordinary sounds are received and registered and brought into connexion with the other parts of the cerebral cortex.³ 2. That the middle part of the auditory centre (first temporo-sphenoidal convolution) in each hemisphere is probably the part of the (main) auditory centre which is concerned, or which is chiefly concerned, with the reception and registration of musical sounds—i.e., is the "auditory tone centre."

But it is doubtful if the auditory centre for ordinary sounds, for musical sounds, and for speech sounds is confined to the first or upper temporo-sphenoidal convolution. Campbell, as I will presently point out, believes that the lower centre for hearing is situated in the transverse temporal gyrus of Heschl. We may term the parts of the main auditory centre in which ordinary sounds and musical sounds are received and registered the *lower* auditory centre. The posterior part of the auditory centre (first temporo-sphenoidal convolution), and probably also the adjacent part of the second temporo-sphenoidal convolution (and perhaps a still more extensive area of the temporo-sphenoidal lobe), is undoubtedly the part of the auditory centre in which speech sounds (auditory speech symbols) are, probably after having passed through the lower auditory centre or centres, received, registered, and brought (or chiefly brought) into connexion with other parts of the cerebral cortex.⁴

In most normal individuals the auditory speech centre, or the *higher* auditory centre, as it may also be termed, is chiefly, and in some persons perhaps only, active on the left side of the brain. It is obvious, because of the much larger number of different sound combinations (spoken words) which it has to register and to bring into connexion with so many other parts of the cerebral cortex, that the higher auditory centre (the auditory speech centre) must be a much larger and a much more elaborate mechanism than the lower auditory centre. It seems to me not unreasonable to suppose that auditory speech symbols (spoken words) are first received and registered in the lower auditory centre or centres in which they are heard, so to speak, merely as sounds and combinations of sounds. But whether this is so or not, it is certain that in order that they may be understood (interpreted as speech symbols), i.e., in order that they may be brought into connexion with associated ("ideational") centres in other parts of the cerebral cortex (in which the memories of object-percepts and other percepts are stored), they must reach and pass through the higher auditory centre—i.e., the auditory speech centre.

¹ In this case the patient, though able to hear, differentiate, and understand both ordinary (non-musical) sounds and speech sounds, was completely tone deaf, as it has been termed. This case seems to suggest (a) that a special part of the auditory centre is concerned with the reception and registration of musical sounds; and (b) that part of the first temporo-sphenoidal convolution on both sides of the brain.

² The report produced by the discharge of a pistol, a shot gun, a rifle, and a small field gun can all be easily differentiated by an experienced observer, and in order that they may be differentiated a connexion must be formed between the cell groups of the auditory centre, in which they are received and registered, and the cell groups in other parts of the cerebral cortex (more especially of the visual cortex), in which the visual and other memories of the particular kind of gun the discharge of which the observer knows by experience is associated with a particular report are stored. But whether these connexions are established in the lower auditory centre or in a part of the higher auditory centre is doubtful. The connexion is probably as Bastian terms it.

³ By this statement I do not mean to imply that the portions of the main auditory centre (the cortical centre for hearing taken as a whole), which I have termed the higher and lower auditory centres, are sharply defined and separated one from the other. Possibly the cell and fibre mechanisms concerned with the hearing of ordinary sounds, though chiefly located in one part, may be more or less diffuse throughout the whole of the auditory centre. It seems certain, however, that the cell and fibre mechanisms, in which the memories of auditory speech symbols are stored, are situated, or chiefly situated, in the posterior part (half or two-thirds) of the first and in the adjacent part of the second temporo-sphenoidal convolutions. Further, it is not speech centres that part of the cortex in which auditory speech symbols are brought into connexion with the other parts of the cortex, may be a part of the temporo-sphenoidal lobe. I will return to this point later. In Bastian has applied to certain areas of the brain cortex which are in close juxtaposition to those portions of the cortex to which the term

In his recently published and most important research, entitled, "Histological Studies on the Localisation of Cerebral Function" (Chapter VI.), Campbell concludes, and to my mind gives very strong grounds for concluding: (1) that the area of cortex laid down for the primary reception of simple auditory stimuli is that which he has mapped out and described as mainly covering the transverse temporal gyri of Heschl; this he terms the audito-sensory area; and (2) that the posterior three-fifths of the free surface of the first temporal gyrus is a second auditory centre specialised for the interpretation and further elaboration of primary auditory stimuli; this area, which forms a skirt for the audito-sensory area, he terms the audito-psycho area (see Fig. 7).

(b) Destruction of the left auditory speech centre, though it may produce complete word deafness (which is rarely, if ever, permanent), certainly does not produce complete and permanent deafness to ordinary sounds in either ear and does not necessarily produce tone deafness or auditory amusia. Hence we must conclude, whatever view we take as to the decussation of the auditory nerve (whether we believe the decussation to be complete or incomplete), that ordinary sounds (and musical sounds) are received and registered in some other portion of the auditory centre than that special part which we term the auditory speech centre. We may term this part of the general auditory centre in which ordinary sounds are received and registered, the *lower centre for hearing*; and there must, of course, be a

FIG. 7.

Drawing of left cerebral hemisphere (human) with Sylvian fissure opened out. (After A. W. Campbell.) Showing (1) the audito-sensory area (shaded) confined to the two transverse temporal gyri and not extending on to the insula, (2) the audito-psycho area (large dots) on the free surface of the posterior three-fifths of the first temporal gyrus, and (3) the extent, on the lateral surface of the hemisphere, of the common temporal cortex (small dots). S. C. I. = sulcus centralis insulae, R. H. S. = ramus horizontalis Sylvii, R. A. S. = ramus ascendens Sylvii, Prec. Inf. = sulcus precentralis inferior, P. O. = parieto-occipital fissure, R. O. T. = ramus occipitalis transversus, T. H. = sulcus temporalis secundus.

THE COURSE OF THE AUDITORY PATH; SEMI- OR PARTIAL DECUSSATION OF THE AUDITORY NERVE.

An analysis of the clinical phenomena presented by cases of disease in man seems to show that the nervous impulses concerned in the hearing, both of ordinary sounds and of speech sounds (spoken words), are carried by each auditory nerve to both auditory centres. The grounds for this conclusion are—

(a) Sudden and complete destruction of the left auditory speech centre results in the production of word deafness³ but destruction of one auditory nerve (or, what is the same thing, complete deafness in one, in either ear) does not produce word deafness. Consequently, in those persons in whom the auditory speech centre is only active on the left side of the brain, and for the sake of simplicity I am supposing that this is the case, the auditory impressions representing words, which enter by either—say the left—ear, must ultimately arrive at the left auditory speech centre.⁴

³ The word deafness is, as we shall afterwards see, in many cases incomplete and more or less quickly recovered from, presumably owing to the fact that the auditory speech centre in the right hemisphere is able to take up and carry on the function of the left auditory speech centre which is destroyed.

⁴ Reasoning on these facts Lichtheim concluded that the decussation of the fibres of the auditory nerve cannot be complete and that the form of word deafness which is termed sub-cortical (which I term sub-central) "can obviously come into existence only if the irradiations of both acoustic nerves in the left temporal region are broken through." Bastian disputes these conclusions. He states that a semi-decussation of the auditory nerve has not been proved anatomically, he thinks that the decussation of the auditory nerve is complete and that auditory impressions which enter through one—say the left—ear ultimately reach the left auditory speech centre through the corpus

callosum, in other words that they first pass to the right auditory speech centre and thence across the corpus callosum to the left auditory speech centre. I agree with Lichtheim (though not exactly for the reasons which he gives) that the decussation of the auditory nerve is incomplete—in other words, that the auditory nerve on one—say the left—side carries auditory impressions to both auditory centres. As stated above, it is probable, I think, that the nervous impulses which convey, so to speak, spoken words, first pass to the lower auditory speech centres on both sides of the brain and then to the auditory speech centre in the left hemisphere, further, it is certain that sub-central auditory aphasia may be, and probably in most instances is, produced in other ways than that which Lichtheim supposes. I will return to this point in the next lecture.

proved by the following facts.—

(c) Complete and permanent deafness in one—the opposite ear very rarely, if ever, results from a localised lesion in any part of the cerebral cortex. So far as I know there are no facts to show that destruction of either the lower or the higher auditory centre, in one hemisphere, ever produces complete and permanent deafness in the opposite ear, as it would necessarily do if the decussation of the auditory nerve were complete. The deafness which results from destruction of the cortical centre for hearing on one side of the brain is usually only partial, and even if it should be complete immediately after the occurrence of the lesion it never, so far as I know, remains complete, it is always in some degree, and almost always, so far as I know, in a

very large degree, recovered from. The rapid recovery is no doubt due to the fact that the cortical centre for hearing in the opposite hemisphere takes up and carries on the functions of the centre which is destroyed. Now, it could only do so if the decussation were incomplete.

(d) Again, we know that this arrangement (semi- or partial decussation) occurs in the case of the optic and of the olfactory and probably also of the gustatory nerves. There is presumptive evidence therefore that the same plan of construction which obtains in the case of the optic nerve and of the olfactory nerve, and probably also of the gustatory nerve, holds good in the case of the auditory nerve.*

(e) Further, actual observation seems to show that a partial or semi-decussation of the auditory nerves does actually occur. Alexander Bruce, for example, states: "The cochlear root terminates in the anterior accessory nucleus of Meynert (or cochlear nucleus) and the tuberculum acusticum, a narrow nucleus continuous with the former, and lying like a cap on the restiform body. From these nuclei secondary connexions are formed through the corpus trapezoidum and the striæ acusticæ. The corpus trapezoidum sends fibres to the superior olives of both sides, to both posterior corpora quadrigemina, and to the opposite internal corpus geniculatum." This last-named structure is directly connected with the superior temporal gyrus by fibres which complete the central path for hearing. This is further strengthened by connexions of each posterior corpus quadrigeminum with the internal geniculate body of its own side (see Fig. 8). The

FIG. 8.

Diagram of the central path for hearing, showing the channels by which auditory impressions reach both hearing centres in the cerebral cortex (after A. Bruce). VIII.C.R. = cochlear root. VIII.C.N. = cochlear nucleus. CT = corpus trapezoidum. S.O. and S.O. = superior olive, left and right. L.F. and L.F. = lateral fissure, left and right. C.A.T. = central auditory tract on the left side, right; C.A.T. = central auditory tract on the right side, left. P.C.Q. and P.C.Q. = posterior corpus quadrigemina: left and right. A.C.Q. = anterior corpus quadrigemina: left and right. I.G.B. and I.G.B. = internal geniculate body, left and right. S.T.G. and S.T.G. = superior temporal gyrus, left and right.

path of the striæ acusticæ is not so well established. They can be followed from the tuberculum acusticum inwards across the floor of the fourth ventricle to the raphe where they pass directly forwards. According to Kölliker they pass round the pyramids of the upper medulla and enter

the restiform body of the opposite side. This view still awaits confirmation."*

THE FUNCTION OF THE AUDITORY SPEECH CENTRE.

The auditory speech centre seems to be: 1. A centre, in which auditory speech symbols (after they have passed through the lower auditory centre, where they are perceived merely as sounds) are received, registered, and brought into relationship by connecting fibres with the associated "ideational" centres; the other centres of the cerebral cortex in which the meaning of words (object-percepts and other percepts) is received, registered, and stored. (see Fig. 2, Lecture I.).

2. A centre through which (i.e., from which) the nervous impulses concerned in the production of repeated (echoed) speech pass in order to reach the vocal speech centre (see Fig. 9). This at all events is the view of most authorities. Its correctness is, I think, doubtful; it is doubtful whether it holds good in all cases. It is probable, I think, that in certain circumstances, and perhaps in some individuals at all events, the nervous impulses concerned in the production of repeated (echoed) speech pass through the lower auditory centre (and not through the higher or auditory speech centre) to the vocal speech centre (i.e., along the dotted lines, from I.a.c. and I.a.c.' to Vo.S.C. in Fig. 9). This

FIG. 9.

ECHOED SPEECH—MEANING NOT UNDERSTOOD

Diagrammatic representation of the course which the nervous impulses concerned in the production of repeated or echoed speech take. In ordinary circumstances the nervous impulses concerned in repeated and echoed speech, after passing to the auditory speech centre (A.S.C.) through the lower auditory centres (I.a.c. and I.a.c'), pass from the auditory speech centre (A.S.C.) to the vocal speech centre (Vo.S.C.), and thence outwards through the lower vocal centres (L.V.C. and I.V.C.) to the lips, tongue, larynx, &c. as shown by the solid lines in the figure. But it is possible, I think, that in certain circumstances (i.e., after destruction of the auditory speech centre) repeated or echoed speech may still be carried out through the dotted lines which pass from the lower auditory centres (I.a.c. and I.a.c') to the vocal speech centre (Vo.S.C.).

point is of considerable importance, as we shall see when I come to describe the points of distinction between the different forms of auditory aphasia.

3. A centre in which (it seems probable, so far as our present knowledge enables us to judge), in most normal individuals and in ordinary circumstances at least, thoughts and ideas are first put into concrete speech form in order that they may be transmitted to the vocal speech centre. The nervous impulses concerned in the production of spontaneous vocal speech seem to pass directly from the

* I may add that the plan of construction of the cerebral nervous mechanisms connected with vision (i.e., the fact that there are undoubtedly lower and higher centres for vision in the cerebral cortex) is also suggestive of the fact that there are both higher and lower centres for hearing.

* Campbell says the middle geniculate body.

very large degree, recovered from. The rapid recovery is no doubt due to the fact that the cortical centre for hearing in the opposite hemisphere takes up and carries on the functions of the centre which is destroyed. Now, it could only do so if the decussation were incomplete.

(d) Again, we know that this arrangement (semi- or partial decussation) occurs in the case of the optic and of the olfactory and probably also of the gustatory nerves. There is presumptive evidence therefore that the same plan of construction which obtains in the case of the optic nerve and of the olfactory nerve, and probably also of the gustatory nerve, holds good in the case of the auditory nerve.*

(e) Further, actual observation seems to show that a partial or semi-decussation of the auditory nerves does actually occur. Alexander Bruce, for example, states: "The cochlear root terminates in the anterior accessory nucleus of Meynert (or cochlear nucleus) and the tuberculum acusticum, a narrow nucleus continuous with the former, and lying like a cap on the restiform body. From these nuclei secondary connexions are formed through the corpus trapezoidum and the striæ acusticæ. The corpus trapezoidum sends fibres to the superior olives of both sides, to both posterior corpora quadrigemina, and to the opposite internal corpus geniculatum.[†] This last-named structure is directly connected with the superior temporal gyrus by fibres which complete the central path for hearing. This is further strengthened by connexions of each posterior corpus quadrigeminum with the internal geniculate body of its own side (see Fig. 8). The

FIG. 8.

Diagram of the central path for hearing, showing the channels by which auditory impressions reach both hearing centres in the cerebral cortex (after A. Bruce). VIII.C.R. = cochlear root, VIII.C.N. = cochlear nucleus, C.T. = corpus trapezoidum; S.O. and S.O. = superior olive, left and right, L.F. and L.F. = lateral fissure, left and right; C.A.T. = central auditory tract on the left side, P.C.Q. and P.C.Q. = posterior corpus quadrigeminum, left and right; A.C.Q. = anterior corpus quadrigeminum, I.G.B. and I.G.B. = internal geniculate body, left and right; S.T.G. and S.T.G. = superior temporal gyrus, left and right.

path of the striæ acusticæ is not so well established. They can be followed from the tuberculum acusticum inwards across the floor of the fourth ventricle to the raphe where they pass directly forwards. According to Kölliker they pass round the pyramids of the upper medulla and enter

the restiform body of the opposite side. This view still awaits confirmation."

THE FUNCTION OF THE AUDITORY SPEECH CENTRE.

The auditory speech centre seems to be: 1. A centre, in which auditory speech symbols (after they have passed through the lower auditory centre, where they are perceived merely as sounds) are received, registered, and brought into relationship by connecting fibres with the associated "ideational" centres; the other centres of the cerebral cortex in which the meaning of words (object-percepts and other percepts) is received, registered, and stored. (see Fig. 2, Lecture I.).

2. A centre through which (i.e., from which) the nervous impulses concerned in the production of repeated (echoed) speech pass in order to reach the vocal speech centre (see Fig. 9). This at all events is the view of most authorities. Its correctness is, I think, doubtful; it is doubtful whether it holds good in all cases. It is probable, I think, that in certain circumstances, and perhaps in some individuals at all events, the nervous impulses concerned in the production of repeated (echoed) speech pass through the lower auditory centre (and not through the higher or auditory speech centre) to the vocal speech centre (i.e., along the dotted lines, from l.a.c. and l.a.c.' to Vo.S.C. in Fig. 9). This

FIG. 9.

ECHOED SPEECH—MEANING NOT UNDERSTOOD

Diagrammatic representation of the course which the nervous impulses concerned in the production of repeated or echoed speech take. In ordinary circumstances the nervous impulses concerned in repeated and echoed speech, after passing to the auditory speech centre (A.S.C.) through the lower auditory centres (l.a.c. and l.a.c'), pass from the auditory speech centre (A.S.C.) to the vocal speech centre (Vo.S.C.) and thence outwards through the lower vocal centres (l.v.c. and l.v.c') to the lips, tongue, larynx, &c. as shown by the solid lines in the figure. But it is possible, I think, that in certain circumstances (i.e., after destruction of the auditory speech centre) repeated or echoed speech may still be carried out through the dotted lines which pass from the lower auditory centres (l.a.c. and l.a.c') to the vocal speech centre (Vo.S.C.).

point is of considerable importance, as we shall see when I come to describe the points of distinction between the different forms of auditory aphasia.

3. A centre in which (it seems probable, so far as our present knowledge enables us to judge), in most normal individuals and in ordinary circumstances at least, thoughts and ideas are first put into concrete speech form in order that they may be transmitted to the vocal speech centre. The nervous impulses concerned in the production of spontaneous vocal speech seem to pass directly from the

* I may add that the plan of construction of the cerebral nervous system is such, as to ensure the fact that there are no centres for vision in the cerebral cortex which are both higher and lower centres for hearing.

† Campbell says the middle geniculate body.

auditory speech centre to the vocal speech centre (see Fig. 10).

4. A centre to which (it seems probable, so far as our present knowledge enables us to judge), in most normal individuals and in ordinary circumstances at least, visual or written speech symbols pass in order that they may be

FIG. 10.

Diagrammatic representation of the course which the nervous impulses concerned in the production of spontaneous vocal speech take. In ordinary circumstances the nervous impulses pass from C.C. to A.S.O. (auditory speech centre), from which they pass through the solid line to the vocal speech centre (V.O.S.C.) and thence out in the ordinary manner. If, however, the auditory speech centre (A.S.O.) is destroyed it is probable that compensation may be effected by the nervous impulses passing from C.C. to the vocal speech centre, either through the visual speech centre (V.I.S.C.) or directly as is represented by the dotted line.

brought into connexion with the associated ("ideational") centres (see Fig. 11).

5. A centre in which (it seems probable, so far as our present knowledge enables us to judge), in most normal individuals and in ordinary circumstances at least, thoughts and ideas are first put into concrete speech form in order that they may be transmitted to (a) the visual speech centre and (b) the graphic speech centre.

It seems probable, so far as our present knowledge enables us to judge, that in most normal individuals the nervous impulses concerned in the production of spontaneous written speech pass indirectly from the "ideational" centres to the visual and graphic speech centres—i.e., through the auditory speech centre to the visual speech centre from which they finally pass to the graphic centre (see Fig. 12). In other words, that thoughts which are to be expressed in written speech are first put into concrete speech form in the auditory speech centre, from which they pass to the visual speech centre, in which they are translated into visual speech symbols, and from the visual speech centre they pass to the graphic ('speech') centre from which they are emitted in the form of the nervous impulses required for the production of the necessary movements concerned in the required written speech (graphic) characters.

It will be noticed that I speak with hesitation and qualification regarding several of the previous headings. It is probable, I think, that in some normal individuals (in persons who are, as it is termed, strong "visuals," and perhaps in many persons after the act of reading has become so well trained as to be, so to speak, automatic) the nervous impulses concerned in reading with understanding and spontaneous writing may pass directly, in the case of reading, from the visual speech centre to the "ideational" centres, and, in the case of spontaneous writing, from the "ideational" centres to the visual speech centre and

so to the writing centre along the dotted lines in Figs. 11 and 12 (and not indirectly—i.e., through the auditory speech centre along the course of the solid lines in Figs. 11 and 12). If this were so, destruction of the auditory speech centre would not disturb the action of the visual speech centre and would not entail defects in reading and writing (as it usually seems to do). It seems certain that, if the auditory speech centre is destroyed, the visual speech centre can (in many cases at least) be trained to play directly upon the "ideational" centres; and that in this way defects in reading and writing, which may be present in the early stages of cases of word deafness due to destruction of the auditory speech centre, can be compensated. Nevertheless, it seems highly probable that, in ordinary circumstances and in most normal individuals, the auditory, visual, and kinesthetic speech centres are so closely linked together that the active functioning of any one of them is attended with some change in the functional activity of the others and, *vice versa*, a lesion, more especially a suddenly developed lesion, in any one of these centres will probably (in most individuals at least) produce some functional derangement in the action of the others, though the degree of that derangement will doubtless vary in accordance with the speech

FIG. 11.

READING WITH UNDERSTANDING

Diagrammatic representation of the course which the nervous impulses concerned in reading with understanding take. The visual impressions pass from the eye to the lower visual centres (V.I.C. and V.I.C.) from which they pass to the visual speech centre (V.I.S.C.); from the visual speech centre the nervous impulses then probably pass to the auditory speech centre (A.S.O.) and from the auditory speech centre to the associated "ideational" centres (C.C.) as is represented by the solid line; but in certain individuals and in some cases of disease, as, for example, where the auditory speech centre or the commissural connexion between the visual speech centre and auditory speech centre is destroyed, the nervous impulses after reaching the visual speech centre (V.I.S.C.) may probably pass directly to the associated "ideational" centres (C.C.) as is represented by the dotted line.

centre which is primarily affected (being greatest, for example, when the auditory speech centre is the seat of the lesion) and with the special functional endowments of the individual (i.e., whether he is an "auditive," a "visual," or a "kinesthetic").

That the auditory, visual, and kinesthetic speech centres are so closely linked together that the active functioning of any one of them is attended with some change in the functional activity of the others seems proved not only by the clinical symptoms which result from localised lesions of these centres, but also by the fact that while learning to read and write the child usually in the act of reading letters and words at the same

expect: 1. Abolition of the power of understanding auditory speech symbols (spoken words) and what, practically speaking, amounts to the same thing, inability to identify (pick out by the aid of the other senses, sight, touch, smell, or taste) an object or written word named. 2. Defects in the production of vocal speech (repeated and spontaneous) (see Figs. 2 and 9). 3. Defects in the power of understanding written speech symbols, in reading, and of vocally repeating written speech symbols—i.e., reading aloud (see Fig. 13). 4. Defects in the production of written speech (spontaneous writing and writing to dictation) (see Fig. 14). 5. Inability to name objects presented to the other senses (objects seen, touched, smelt, tasted) (see Fig. 15).

THE RELATIONSHIP OF THE AUDITORY SPEECH CENTRE TO
THE "IDEATIONAL" CENTRES AND THE PROCESS
OF THOUGHT.

That the auditory speech centre is a centre in which auditory speech symbols (word percepts) are brought into connexion with the memory pictures (ideas, the object and other percepts) which are stored in the other centres of the cerebral cortex—the "ideational" centres—seems to be confirmed by a study of the development of speech in the child.

READING ALOUD

Diagrammatic representation of the course which the nervous impulses concerned in reading aloud take. The nervous impulses pass from the eye through the lower visual centres to the visual speech centre, thence, in ordinary circumstances, and in most normal individuals, they would seem to pass to the auditory speech centre and from the auditory speech centre to the associated "ideational" centres (C.C.), where their meaning is fully understood in consciousness. From the "ideational" centres (C.C.) the nervous impulses then pass to the auditory speech centre and out in the ordinary way through the vocal speech centre and lower vocal centres—i.e., through the solid lines in the figure. If the meaning of the words is not fully understood the nervous impulses after reaching the auditory speech centre pass directly to the vocal speech centres—i.e., without passing to the "ideational" centres (C.C.); or perhaps in some cases directly from the visual speech centre (V.S.C.) to the vocal speech centre (V.O.S.C.), through the dotted line in the figure—i.e., without passing through the auditory speech centre.

Long before the infant forms any intelligent idea of speech sounds and visual pictures (objects) he is able to perceive noises and visual impressions of light, form, and colour. These elementary auditory and visual impressions are no doubt received and registered in the lower auditory and visual (half-vision) centres. The young child next learns to perceive and intelligently to recognise objects and speech sounds. He is then taught to form associations in consciousness, or associations in consciousness are spontaneously formed (without teaching), between the impressions which reach the brain through these two different

THE EFFECTS OF DESTRUCTION OF THE AUDITORY SPEECH CENTRE.

Now, if the auditory speech centre is possessed of the functions which have just been enumerated, sudden and complete destruction of the auditory speech centre should, in most normal individuals (theoretically, at least), produce the effects enumerated below and, speaking generally, such is the case, but for reasons which have just been indicated and which will be afterwards explained in more detail, some of these defects are in many cases much less marked than one might at first sight and on theoretical grounds

sensory channels. The child sees the object "dog," and his mother names the object "dog" or "bow-wow." When this procedure has been frequently repeated the child comes to associate the auditory speech symbol "dog" or "bow-wow" with the object "dog." And it must be remembered that not only is an intimate connexion formed in consciousness between these two sensory impressions, but—what is, I think, a very remarkable fact when we remember that it applies to the most intricate processes which take place in the marvellously intricate nervous mechanisms of the brain—an actual physical connexion—a nerve connexion is

FIG. 14.

Diagrammatic representation of the course which the nervous impulses concerned in writing to dictation take. If the meaning of the words is understood the nervous impulses after reaching the auditory speech centre (A.S.C.) pass to the associated "Ideational" centres (I.O.C.); then from the "Ideational" centres back to the auditory speech centre; thence to the visual speech centre (V.I.S.C.) and from the visual speech centre to the graphic speech centre (G.S.C.) and out in the ordinary way through the lower graphic centres to the right hand. If the meaning of the words is not understood the nervous impulses may, after reaching the auditory speech centre, pass to the visual speech centre and thence out to the graphic speech centre, i.e. without passing to the "Ideational" centres (I.O.C.), or perhaps in some conditions of disease directly from the auditory speech centre (A.S.C.) to the graphic speech centre (G.S.C.), as is represented by the dotted line in the figure.

formed between the cell group in the higher auditory centre which represents the word "dog" or "bow-wow," and the cell group in the visual centre which receives and registers the image of the object "dog." After frequent repetition the connexion becomes so perfect, the connecting tracts so well worn, that whenever the child hears the sound (word) "dog" or "bow-wow" he looks about for, and fixes his eyes upon, the object—the dog; or, if the object is not present, he mentally pictures to himself (i.e., thinks of) the object—it raises up in the mind the memory or mental picture of the object "dog." In other words, the stimulus which is in this case primarily received by the cell group in the auditory centre which represents the sound (word) "dog" flows over from the auditory speech centre to the associated cell group in the visual centre and excites the visual memory of the object "dog." This is the basis of all intellectual operations—the association of ideas. So, too, whenever the child sees the object "dog" the stimulus flows over from the cell group in the visual centre, which receives it, to cell group in the auditory centre, the auditory speech centre the associated cell group in the auditory speech centre in which the auditory speech symbol "dog" or "bow-wow" is represented; this cell group is in its turn stimulated and a memory of the word (name) "dog" or "bow-wow" is excited—the child thinks of the auditory speech symbol, the name "dog" or "bow-wow." The two centres (the visual

centre and the auditory speech centre) are in this way concurrently educated and taught to play one upon the other. By this process intimate connexions are formed between cell groups in these two great sensory centres (the visual and the higher auditory centres) and the names of various objects are taught and learned. In other words, the auditory speech symbols are not only brought into conscious relationship with the ideas which they symbolise and represent but the cell groups in the auditory speech centre in which the auditory speech symbols are received and registered are brought into anatomical and physiological relationship with the cell groups in the visual centre in which the visual impressions to which they correspond—i.e., which they symbolise—are received and registered.

The acquisition of attributes.—After a certain degree of education of the auditory speech centre, the visual centre, and the vocal speech centre (the centres concerned in the recognition of objects and movements (certain actions), in the comprehension and in the production of certain of the speech sounds (nouns and certain verbs expressive of certain actions) which represent the objects and visible movements which have been brought into organic cohesion and conscious association) has been acquired, information derived from the other sensory cerebral centres (the education of which has also been in process of development) is

FIG. 15.

Diagrammatic representation of the course which the nervous impulses concerned in the naming of an object or written word at sight take. In naming a written word at sight the nervous impulses pass from the eye to the lower visual centres and thence to the visual speech centre (V.I.S.C.), from which they pass to the auditory speech centre (A.S.C.), then, if they are understood, they pass to the associated "Ideational" centres (I.O.C.), from which they pass back to the auditory speech centre (A.S.C.) and thence out to the vocal speech centre (V.O.S.C.) in the ordinary manner (through the solid lines in the figure). If, however, the written word is not understood the impulses after reaching the visual speech centre (V.I.S.C.), and passing to the auditory speech centre (A.S.C.) without passing to the vocal speech centre (V.O.S.C.) pass directly to the associated "Ideational" centres (I.O.C.); or perhaps in certain circumstances directly from the visual speech centre (V.I.S.C.) to the vocal speech centre (V.O.S.C.), as is represented by the dotted lines in the figure. In naming an object (not a written word) at sight the nervous impulses after reaching the lower visual centres pass to a higher visual centre (not represented in the diagram), and from this higher visual centre they pass to the auditory speech centre (A.S.C.) and thence out in the ordinary way.

brought into the connexion and the child learns to associate certain qualities or attributes with the objects which he recognises by the eye and the names of which he has come to recognise by the ear. He is taught, for example, to associate such speech sounds (adjectives) as

"sweet" and "nice" with objects, such as sugar, which taste sweet and which he likes. In other words, the conscious impression which is generated in the cell group in the gustatory centre, which is stimulated by the application of the substance sugar to the end-organs of the nerves of taste, is brought into relationship with the cell group in the auditory centre which is stimulated by the sound (word) "sweet" or "nice." As the child's experience enlarges he comes to associate, and is taught to associate, the terms (words) "sweet" and "nice," not only with the taste of sugar, but with everything which he likes—say with "papa," "mama," &c. He also learns to form contrasts, to compare such substances as sugar and salt and such terms as *nice* and *nasty*. In this way, through the different senses and through the cerebral connexions which are formed between the different sensory centres, the child gradually learns (acquires) a large number of different attributes (adjectives), such as *sweet*, *bitter*, *nice*, *nasty*, *good*, *bad*, *soft*, *hard*, *rough*, *smooth*, and so on.

It is doubtful whether—when the attribute has acquired a sufficiently wide meaning—the stimulation of the cell group, say in the gustatory centre, in which the memory picture of the (sweet) taste of sugar was originally implanted and stored (which results from the overflow, so to speak, from the cell group in the auditory speech centre corresponding to the word "sweet"), is sufficiently powerful to excite a conscious sensation—i.e., a memory of a sweet taste. The connexion between the two cell groups in the auditory speech centre which represent the terms "sweet" and "sugar" must, of course, be much more powerful, for—although few persons, if any, feel a conscious gustatory sensation (taste) of sweetness when either the one or the other term (*sweet* or *sugar*) is thought of¹⁰—whenever we talk of "sweet" we are prone to (inclined to) think of sugar—the type of a sweet thing, the original thing with which we associated the sensation of sweetness, and *vice versa*.

When the word "*sweet*" calls up in the mind the memory of sugar the nervous process is probably as follows. The cell group in the auditory speech centre representing the word *sweet* is first stimulated; the stimulation then passes to the closely associated cell group in the auditory speech centre, the term or word *sugar*; and then if the ideas (gustatory, visual, &c.) which represent the thing *sugar* are called up in the mind the stimulation passes to distant cell groups in the gustatory, visual, and other cortical centres in which the ideas which go to form the complex mental picture or idea of (in this case) the thing *sugar* are represented and stored. In this way connexions may be formed between cell groups in the auditory speech centre and cell groups in the other sensory centres in the cerebral cortex. The child, for example, learns to associate with the auditory symbol or word percept "*orange*," certain visual appearances representing the form, size, shape, and colour of the orange, and certain gustatory, olfactory, tactile, and kinæsthetic impressions representing the taste, smell, feel, and weight of the orange. When this process is completed the raising up in the mind of the auditory speech symbol—in other words, the stimulation of the cell group in the auditory speech centre representing the word "*orange*"—raises up in the mind, or may raise up in the mind, all the attributes of the orange which the individual has by experience learned or acquired, the memory pictures of which have been stored (imprinted) in other parts of the cerebral cortex. In other words, there is an overflow from the cell group in the auditory speech centre which represents the auditory speech symbol or word percept "*orange*," through the connecting fibres, either directly or indirectly, to many different associated centres in the cerebral cortex; and the stimulation of the associated cell groups in these different centres is attended in consciousness with the revival of the memory pictures of the different qualities or attributes of an orange with which the individual has by previous experience become acquainted.

The process of learning to understand speech sounds (spoken words) seems to consist, so far as the physical side of the process is concerned, in the formation of connexions

between (a) the cell groups of the auditory speech centre, in which the word percepts are stored, and (b) the cell groups of the other centres of the cortex, in which the object and other percepts which represent the ideas which the word percepts (names) symbolise are stored. In the case of highly complex abstract ideas the process is necessarily much more elaborate than the simple process which I have just described. Further, it must be remembered that in the auditory speech centre itself connexions are formed between different cell groups representing the synonyms of different word percepts which in the experience of the individual represent the same idea or ideas. Taking the simple illustration, for example, which has been already given, there must obviously be in the auditory speech centre of the child two cell groups corresponding to the words "*dog*" and "*bow-wow*." Again, to give another example, the auditory word percepts "*sweet*," "*nice*," "*agreeable*," "*pleasant*," which symbolise or which may symbolise the same idea, must all have cell groups in the auditory speech centre which are in intimate anatomical and physiological (physical) connexion one with another. Again, the same speech sound may have entirely different meanings in accordance with the context (the other speech sounds with which it is associated), and the intonation which is given to the sound—witness, for example, the word "*dam*" in the sentences, "*The dam in the river is, &c.*," "*Damn that boy.*" "*The river was dammed.*" "*Go and be damned.*" These considerations clearly show that the auditory speech centre must be a very elaborate nervous mechanism.

According to the view which has just been stated, the memory or mental pictures of auditory speech symbols or names (word percepts) of objects, attributes, ideas, &c., are stored in the auditory speech centre, but the memory pictures of the ideas which these names represent are not raised in the mind by mere stimulation of the nervous mechanisms (cell groups) in the auditory speech centre, in which the memory pictures of the auditory speech symbols (words) are stored. The revival in consciousness of the memories of the ideas which the word percepts symbolise necessitates an overflow of nervous impulses to, and the stimulation of, the corresponding cell groups in the associated ("ideational") centres, which are situated in other, and it may be very distant, parts of the cerebral cortex. It, of course, does not necessarily follow, although this no doubt may be the case, when we hear the name "*orange*" and we afterwards think of the different attributes or qualities of an orange, that all of the nervous impulses pass *directly* from the cell group in the auditory speech centre, representing the word "*orange*," to the associated cell groups in the other (ideational) centres in which the memory pictures of the qualities or attributes of the "*orange*" are stored. The process may be, and probably in most instances is, an indirect one. The word "*orange*" may raise up the visual picture (shape, size, colour) of an orange and the stimulus may next pass from the cell groups in the *visual* centre, in which these visual memory pictures of the orange are stored, say to the cell group in the gustatory centre in which the memory picture of the taste of the orange is stored; and from that centre to an associated cell group in the auditory speech centre in which the memory picture of the auditory speech symbol "*sour*" is stored, which will then be stimulated. Further, it is, of course, possible that the stimulus may pass from the cell group in the auditory speech centre in which the memory picture "*orange*" is stored to an associated cell group in the same centre—the auditory speech centre—in which the memory picture of the word "*sour*" is stored, provided the memory pictures (word percepts) of the terms *orange* and *sour* which are at rest in these two cell groups have become sufficiently linked together in consciousness and that the nervous overflow may pass from the cell group in the auditory centre which represents the word *sour* to the cell group in the gustatory centre in which the memory picture of the (sour) taste of an orange is stored. The view which I have advocated with regard to the relationship of the auditory speech centre and the "ideational" centres is not accepted by all authorities.

BROADBENT'S VIEW AS TO A NAMING OR IDEA CENTRE.

¹⁰ The uncertainty as to whether the original cell group in the sensory centre (say in the gustatory centre associated with the sensation of sweetness) must necessarily be (actively or passively) stimulated every time that the term "*sweet*" is subsequently aroused in consciousness is one which is constantly cropping up in connexion with some difficult questions with regard to the physiology and pathological physiology of the speech mechanism.

Broadbent supposes that in addition to the auditory speech centre there is situated in some part of the cerebral cortex another centre which he terms the "*naming*" or "*idea*" centre, in which the combination of the evidence respecting the idea of an external object received through

sensory channels. The child sees the object "dog," and his mother names the object "dog" or "bow-wow." When this procedure has been frequently repeated the child comes to associate the auditory speech symbol "dog" or "bow-wow" with the object "dog." And it must be remembered that not only is an intimate connexion formed in consciousness between these two sensory impressions, but—what is, I think, a very remarkable fact when we remember that it applies to the most intricate processes which take place in the marvellously intricate nervous mechanisms of the brain—an actual physical connexion—a nerve connexion is

FIG. 14.

Diagrammatic representation of the course which the nervous impulses concerned in writing to dictation take. If the meaning of the words is understood the nervous impulses after reaching the auditory speech centre (A.S.C.) pass to the associated "Ideational" centres (C.C.); then from the "Ideational" centres back to the auditory speech centre; thence to the visual speech centre (V.S.C.) and from the visual speech centre to the graphic speech centre (G.S.C.) and out in the ordinary way through the lower graphic centres to the right hand. If the meaning of the words is not understood the nervous impulses may, after reaching the auditory speech centre, pass to the visual speech centre and thence out to the graphic speech centre, i.e., without passing to the "Ideational" centres (C.C.), or perhaps in some conditions of disease directly from the auditory speech centre (A.S.C.) to the graphic speech centre (G.S.C.), as is represented by the dotted line in the figure.

formed between the cell group in the higher auditory centre which represents the word "dog" or "bow-wow," and the cell group in the visual centre which receives and registers the image of the object "dog." After frequent repetition the connexion becomes so perfect, the connecting tracts so well worn, that whenever the child hears the sound (word) "dog" or "bow-wow" he looks about for, and fixes his eyes upon, the object—the dog; or, if the object is not present, he mentally pictures to himself (i.e., thinks of) the object—it raises up in the mind the memory or mental picture of the object "dog." In other words, the stimulus which is in this case primarily received by the cell group in the auditory centre which represents the sound (word) "dog" flows over from the auditory speech centre to the associated cell group in the visual centre and excites the visual memory of the object "dog." This is the basis of all intellectual operations—the association of ideas. So, too, whenever the child sees the object "dog" the stimulus flows over from the cell group in the visual centre, which receives it, to the associated cell group in the auditory speech centre in which the auditory speech symbol "dog" or "bow-wow" is represented; this cell group is in its turn stimulated and a memory of the word (name) "dog" or "bow-wow" is formed—the child thinks of the auditory speech symbol, the excited—the child thinks of the auditory speech symbol, the name "dog" or "bow-wow." The two centres (the visual

centre and the auditory speech centre) are in this way concurrently educated and taught to play one upon the other. By this process intimate connexions are formed between cell groups in these two great sensory centres (the visual and the higher auditory centres) and the names of various objects are taught and learned. In other words, the auditory speech symbols are not only brought into conscious relationship with the ideas which they symbolise and represent but the cell groups in the auditory speech centre in which the auditory speech symbols are received and registered are brought into anatomical and physiological relationship with the cell groups in the visual centre in which the visual impressions to which they correspond—i.e., which they symbolise—are received and registered.

The acquisition of attributes.—After a certain degree of education of the auditory speech centre, the visual centre, and the vocal speech centre (the centres concerned in the recognition of objects and movements (certain actions), in the comprehension and in the production of certain of the speech sounds (nouns and certain verbs expressive of certain actions) which represent the objects and visible movements which have been brought into organic cohesion and conscious association) has been acquired, information derived from the other sensory cerebral centres (the education of which has also been in process of development) is

FIG. 15.

Diagrammatic representation of the course which the nervous impulses concerned in the naming of an object or written word at sight take. In naming an object or written word at sight the nervous impulses pass from the eye to the lower visual centres and thence to the visual speech centre (V.S.C.), from which they pass to the auditory speech centre (A.S.C.), then, if they are understood, they pass to the associated "Ideational" centres (C.C.), from which they pass back to the auditory speech centre (A.S.C.) and thence out to the vocal speech centre (V.S.C.) in the ordinary manner (through the solid lines in the figure). If, however, the written word is not understood the impulses after reaching the visual speech centre (V.S.C.) pass directly to the auditory speech centre (A.S.C.) without passing to the associated "Ideational" centres (C.C.); or perhaps in certain circumstances directly from the visual speech centre (V.S.C.) to the vocal speech centre (V.S.C.), as is represented by the dotted lines in the figure. In naming an object (not a written word) at sight the nervous impulses after reaching the lower visual centres pass to a higher visual centre (not represented in the diagram), and from this higher visual centre they pass to the auditory speech centre (A.S.C.) and thence out in the ordinary way.

brought into the connexion and the child learns to associate certain qualities or attributes with the objects which he recognises by the eye and the names of which he has come to recognise by the ear. He is taught, for example, to associate such speech sounds (adjectives) as

"sweet" and "nice" with objects, such as sugar, which taste sweet and which he likes. In other words, the conscious impression which is generated in the cell group in the gustatory centre, which is stimulated by the application of the substance sugar to the end-organs of the nerves of taste, is brought into relationship with the cell group in the auditory centre which is stimulated by the sound (word) "sweet" or "nice." As the child's experience enlarges he comes to associate, and is taught to associate, the terms (words) "sweet" and "nice," not only with the taste of sugar, but with everything which he likes—say with "papa," "mama," &c. He also learns to form contrasts, to compare such substances as sugar and salt and such terms as *nice* and *nasty*. In this way, through the different senses and through the cerebral connexions which are formed between the different sensory centres, the child gradually learns (acquires) a large number of different attributes (adjectives), such as *sweet, bitter, nice, nasty, good, bad, soft, hard, rough, smooth*, and so on.

It is doubtful whether—when the attribute has acquired a sufficiently wide meaning—the stimulation of the cell group, say in the gustatory centre, in which the memory picture of the (sweet) taste of sugar was originally implanted and stored (which results from the overflow, so to speak, from the cell group in the auditory speech centre corresponding to the word "sweet"), is sufficiently powerful to excite a conscious sensation—i.e., a memory of a sweet taste. The connexion between the two cell groups in the auditory speech centre which represent the terms "sweet" and "sugar" must, of course, be much more powerful, for—although few persons, if any, feel a conscious gustatory sensation (taste) of sweetness when either the one or the other term (*sweet* or *sugar*) is thought of¹⁰—whenever we talk of "sweet" we are prone to (inclined to) think of sugar—the type of a sweet thing, the original thing with which we associated the sensation of sweetness, and *rice* *rené*.

When the word "*sweet*" calls up in the mind the memory of sugar the nervous process is probably as follows. The cell group in the auditory speech centre representing the word *sweet* is first stimulated; the stimulation then passes to the closely associated cell group in the auditory speech centre, the term or word sugar; and then if the ideas (gustatory, visual, &c.) which represent the thing sugar are called up in the mind the stimulation passes to distant cell groups in the gustatory, visual, and other cortical centres in which the ideas which go to form the complex mental picture or idea of (in this case) the thing sugar are represented and stored. In this way connexions may be formed between cell groups in the auditory speech centre and cell groups in the other sensory centres in the cerebral cortex. The child, for example, learns to associate with the auditory symbol or word percept "orange," certain visual appearances representing the form, size, shape, and colour of the orange, and certain gustatory, olfactory, tactile, and kinæsthetic impressions representing the taste, smell, feel, and weight of the orange. When this process is completed the raising up in the mind of the auditory speech symbol—in other words, the stimulation of the cell group in the auditory speech centre representing the word "orange"—raises up in the mind, or may raise up in the mind, all the attributes of the orange which the individual has by experience learned or acquired, the memory pictures of which have been stored (imprinted) in other parts of the cerebral cortex. In other words, there is an overflow from the cell group in the auditory speech centre which represents the auditory speech symbol or word percept "orange," through the connecting fibres, either directly or indirectly, to many different associated centres in the cerebral cortex; and the stimulation of the associated cell groups in these different centres is attended in consciousness with the revival of the memory pictures of the different qualities or attributes of an orange with which the individual has by previous experience become acquainted.

The process of learning to understand speech sounds (spoken words) seems to consist, so far as the physical side of the process is concerned, in the formation of connexions

between (a) the cell groups of the auditory speech centre, in which the word percepts are stored, and (b) the cell groups of the other centres of the cortex, in which the object and other percepts which represent the ideas which the word percepts (names) symbolise are stored. In the case of highly complex abstract ideas the process is necessarily much more elaborate than the simple process which I have just described. Further, it must be remembered that in the auditory speech centre itself connexions are formed between different cell groups representing the synonyms of different word percepts which in the experience of the individual represent the same idea or ideas. Taking the simple illustration, for example, which has been already given, there must obviously be in the auditory speech centre of the child two cell groups corresponding to the words "dog" and "bow-wow." Again, to give another example, the auditory word percepts "sweet," "nice," "agreeable," "pleasant," which symbolise or which may symbolise the same idea, must all have cell groups in the auditory speech centre which are in intimate anatomical and physiological (physical) connexion one with another. Again, the same speech sound may have entirely different meanings in accordance with the context (the other speech sounds with which it is associated), and the intonation which is given to the sound—witness, for example, the word "dam" in the sentences, "The *dam* in the river is, &c.," "*Damn* that boy," "The river was *dammed*," "Go and be *dammed*." These considerations clearly show that the auditory speech centre must be a very elaborate nervous mechanism.

According to the view which has just been stated, the memory or mental pictures of auditory speech symbols or names (word percepts) of objects, attributes, ideas, &c., are stored in the auditory speech centre, but the memory pictures of the ideas which these names represent are not raised in the mind by mere stimulation of the nervous mechanisms (cell groups) in the auditory speech centre, in which the memory pictures of the auditory speech symbols (words) are stored. The revival in consciousness of the memories of the ideas which the word percepts symbolise necessitates an overflow of nervous impulses to, and the stimulation of, the corresponding cell groups in the associated ("ideational") centres, which are situated in other, and it may be very distant, parts of the cerebral cortex. It, of course, does not necessarily follow, although this no doubt may be the case, when we hear the name "orange" and we afterwards think of the different attributes or qualities of an orange, that all of the nervous impulses pass *directly* from the cell group in the auditory speech centre, representing the word "orange," to the associated cell groups in the other (ideational) centres in which the memory pictures of the qualities or attributes of the "orange" are stored. The process may be, and probably in most instances is, an indirect one. The word "orange" may raise up the visual picture (shape, size, colour) of an orange and the stimulus may next pass from the cell groups in the *visual* centre, in which these visual memory pictures of the orange are stored, say to the cell group in the gustatory centre in which the memory picture of the taste of the orange is stored; and from that centre to an associated cell group in the auditory speech centre in which the memory picture of the auditory speech symbol "sour" is stored, which will then be stimulated. Further, it is, of course, possible that the stimulus may pass from the cell group in the auditory speech centre in which the memory picture "orange" is stored to an associated cell group in the same centre—the auditory speech centre—in which the memory picture of the word "sour" is stored, provided the memory pictures (word percepts) of the terms orange and sour which are stored in these two cell groups have become sufficiently linked together in consciousness and that the nervous overflow may pass from the cell group in the auditory centre which represents the word *sour* to the cell group in the gustatory centre in which the memory picture of the (sour) taste of an orange is stored. The view which I have advocated with regard to the relationship of the auditory speech centre and the "ideational" centres is not accepted by all authorities.

BROADBENT'S VIEW AS TO A NAMING OR IDEA CENTRE.

Broadbent supposes that in addition to the auditory speech centre there is situated in some part of the cerebral cortex another centre which he terms the "*naming*" or "*idea*" centre, in which the combination of the evidence respecting the idea of an external object received through

¹⁰ The uncertainty as to whether the original cell group in the sensory centre (say in the gustatory centre associated with the sensation of sweetness) must necessarily be (actively or passively) stimulated every time that the term "sweet" is subsequently aroused in consciousness is one which is constantly cropping up in connexion with some difficult and pathological theologies of mental action; and the same difficulty recurs with regard to the physiology and pathological physiology of the speech mechanism.

all the senses is brought into association with the name of the object. He says:—

There is a primary or rudimentary perceptive act in which the external cause of a given set of sensations is recognised as such and in which the simple attributes, as of form, colour, hardness, &c., are perceived. And there is a higher degree of elaboration in which, by the combination or fusion of perceptions derived from the various organs of sense, a conception or an idea of an object as a whole is obtained. This is a new and distinct process and is usually accompanied by the affixing of a name to the object. To the "perceptive centres" I relegate simply the translation of sensations into rudimentary or primary perceptions and these centres must lie somewhere in the marginal convolutions, which receive radiating fibres from the crus and central ganglia, upon which, therefore, impressions will first impinge and which are symmetrically combined by the fibres of the corpus callosum. The higher elaboration, the fusion of various perceptions together, and the evolution of an idea out of them, will be accomplished not by radiation of an impression from one perceptive centre to all the others but by convergence of impressions from the various perceptive centres upon a common intermediate cell area in which a process analogous to the translation of an impression into a sensation and of a sensation into a primary perception will take place. This intermediate cell area will form a part of the supreme centre and will be situated in the superadded convolutions which receive no radiating fibres.¹¹

And again:—

The formation of an idea of any external object is the combination of the evidence respecting it received through all the senses; for the employment of this idea in intellectual operations it must be associated with, and symbolised by, a name. The structural arrangement corresponding to this process I have supposed to consist in the convergence from all the "perceptive centres" of tracts of fibres to a convoluted area (not identified) which may be called the "Idea Centre" or "Naming Centre." This will be on the sensory, afferent, or upward side of the nervous system, its correlative motor centre will be the "Propositionalising Centre," in which names or nouns are set in a framework of other words for outward expression and in which a proposition is realised in consciousness or mentally rehearsed. If we are to have a seat of the faculty of languages, it would be here rather than in the third left frontal convolution, with which, however, it may possibly be in close proximity. Expressing this by a diagram (see Fig. 16) we have V, A, and T, the visual (angular gyrus, Ferrier),

FIG. 16.

Plan of "naming centre" (after Broadbent).

auditory (infra-marginal Sylvian gyrus), and tactile (uncinate gyrus), perceptive centres sending converging tracts of fibres, *v, n, a, n, t, n*, to N, the "naming centre." Here the perceptions from V and T (smell and taste are omitted for the sake of simplicity) are combined into an idea, which idea is symbolised by the word reaching N through A, which has always, in the experience of the individual, been associated with the object. P is the propositionalising centre in which the phrase is formed, its relations with N and S being sufficiently clear. It will no doubt be objected that there is no evidence of two centres, one for propositionising and the other employed by it for utterance; one for the construction and mental rehearsal of a phrase and the other for realising it in spoken words; and it is unquestionably true that, in a large proportion of cases of aphasia, both faculties are lost. The independence of the two operations seems to me, however, to be established by the following facts: *a*. There are cases in which the patient cannot frame the simplest phrase but can repeat anything said before him. Here S is intact, P destroyed. *b*. The converse of this—namely, that a proposition is realised in consciousness, so that not only the wish but the words are present to the mind, while the expression of them is impossible—is difficult to establish; but a comparison of cases of aphasia has led me to the conclusion that such is sometimes the case. If, however, there are really instances in which speech is lost while the power of writing is retained this would be conclusive. This will be considered later. This diagram (see Fig. 16) will perhaps bring out clearly what is, however, well recognised, the distinction between nouns or names and other parts of speech; the receptive centre, N, has to do only with names; as soon as other words are brought into use a motor function is exercised.¹²

This view seems to me to be quite unnecessary and much less probable than the one which I have advocated. Although it is conceivable that the nervous processes which are the physical substrata of the simple perceptions which represent a simple idea or a concrete thing (such as an orange) might be correlated and focussed together, as it were in a "naming centre," it seems to me very difficult to conceive that the highly complex nervous processes which constitute the physical (nervous) substrata of a highly complex abstract idea, such as the term "government" denotes, could be so focussed. Further, so far as I know, there are no facts to show that a localised lesion in any part of the brain other than the auditory speech centre is capable of completely obliterating the memories of names; in other words, clinico-pathological observations lend, so far as I know, no definite support to Broadbent's view.

In the *Journal of Nervous and Mental Disease* for January, 1895, O. K. Mills and J. W. McConnell reported a case which, they think, supports Broadbent's views and shows that the "naming centre" is situated in the inferior part of the left temporo-sphenoidal lobe. William Elder, in his book on Aphasia, quotes the case and agrees with the deductions which Mills draws from it. With this opinion I am quite unable to agree; the facts of the case do not, in my opinion, warrant the conclusions which the authors base upon them. The details of the case, which are of importance so far as the question of a "naming centre" is concerned, are as follow:—

A married woman, aged about 40 years, was first seen on July 18th, 1894. Two years before she came under observation she seems to have presented some symptoms of word blindness. On examination she was found to be word-blind but not letter-blind; there was apparently (the clinical details are very meagre) agraphia and there was right-sided homonymous hemianopsia. She was unable to name objects either from sight or touch, though she evidently understood what they were. She talked spontaneously but not freely, rarely using concrete nouns and sometimes misplacing words. She had some difficulty in repeating words but there does not appear to have been any word deafness. Six weeks before her death right-sided hemiplegia gradually developed. During the last weeks of her life "yes" and "no" were the only expressions used by her. She died on Sept. 10th, 1894.

Post-mortem examination.—A glommatous tumour was found in the lower part of the left temporo-sphenoidal lobe. "The parts chiefly destroyed were the white matter of the third, to a less extent of the second, and to a still less extent of the fourth temporal convolutions. Internally, the roof of the posterior horn of the lateral ventricle presented a slightly congested and granular appearance." The authors state that "the disease almost certainly started in the third temporal convolution, at a point with the posterior extremity of the horizontal branch of the Sylvian fissure."

Criticism.—I would suggest that the lesion must have been more extensive than the authors state. A destructive lesion limited to the lower part of the left temporo-sphenoidal lobe does not satisfactorily explain the symptoms which the case presented during life (word blindness, agraphia, right-sided homonymous hemianopsia, inability to name objects on sight and touch, and, ultimately, complete motor aphasia and right-sided hemiplegia), more especially when it is remembered that there was no word deafness and that the auditory speech centre was certainly not completely destroyed. The lesion did not involve the first temporal convolution; the second temporal convolution, which is probably a part of the auditory speech centre, was only partly destroyed.

The inability to name objects on sight and touch was probably, I think, due to interruption of the conducting fibres passing between the visual and tactile centres, on the one hand, and the auditory speech centre on the other. That the visual speech centre and the subjacent white fibres were involved seems to be conclusively proved by the facts that the patient was word-blind, agraphic, and affected with right-sided homonymous hemianopsia. Further, the history of the case seems to show that word blindness was present two years before the patient's death. I repeat that, in my opinion the case does not give any support to Broadbent's view; to my mind, it does not afford any proof either of the existence of a "naming centre" or of the position of that centre.

Again, according to Broadbent's theory, if I understand him rightly, destruction of the "naming" centre (N)—the auditory speech centre (A) being unaffected—will not only obliterate the idea, as a whole, which the name symbolises but will produce word deafness for names and will also render the patient unable to intelligently revive the memory pictures of names and spontaneously to make use of names for the purpose of intellectual speech. Now, if this is admitted, destruction of the "naming" or "idea" centre (N) should also destroy the patient's ability intelligently to make use.

¹¹ Transactions of the Royal Medical and Chirurgical Society, vol. xv, 1872, p. 181.

¹² Brain, vol. i., 1879, p. 494.

for the purposes of thought, of the memory pictures which are stored in the visual and tactual centres (V and T), for the centres V and T have, according to Broadbent, exactly the same relationship to the naming centre (N) which the auditory centre (A) has. Such a conclusion seems to be opposed to our knowledge of the working of the brain and of the relationship of speech and thought.

It is, of course, conceivable, if Broadbent's theory were correct, that destruction of the "naming" centre (N) would destroy the combined mental picture of an object—the idea of an object which is formed by the combination in the centre (N) of the primary memory pictures represented in the lower (primary perceptive) centres (A, V, and T). But even if this were so, if destruction of the naming centre (N) were to produce obliteration of the combined memory pictures—the ideas of objects as a whole—I see no reason why destruction of the naming centre (N) should also destroy and prevent the revival of the primary memory pictures stored in the auditory, visual, and tactual centres (A, V, and T); in other words, I see no reason why destruction of the naming centre (N)—the auditory centre (A) remaining unaffected—should render the patient unable to recall and make use of names for the purposes of speech.

It seems to me that the so-called "naming centre" is merely that part of the higher auditory centre (the auditory speech centre or its annexe, as Bastian terms it), in which an elaborate system of connexions is established between certain cell groups representing auditory speech impressions (word percepts) and other portions of the cerebral cortex in which cell groups representing the memory pictures or ideas which those word percepts represent are stored. This view is, I think, confirmed by the process of introspection. When we hear the name of an object, such as an "orange" we do not immediately perceive in consciousness all the attributes of that object; there is an obvious interval between the raising up in the mind of the different attributes (qualities or ideas which the word percept symbolises)—an obvious break or interval in the process of thought which it is reasonable to suppose corresponds to the overflow of the stimulus from one associated centre to another. So, too, when we are asked to express or define what we mean by an abstract idea, such as the term "Government," we cannot immediately express the complicated mental idea which the term involves as it seems to me we ought to be able to do if Broadbent's theory were correct—if the complex ideas which the term "Government" represents were focussed or gathered together in a special "naming" or "idea" centre—we have to take time, and often a long time, to think what the term means, to deliberate, to collect our thoughts before we can define and express what we mean by the term.

The chief argument which has been advanced by Broadbent in favour of the existence of a "naming centre" is the fact that in certain cases of aphasia the patient is absolutely unable to make use of names, whereas he retains the ability to make use of other parts of speech in which names, as Broadbent puts it, are set in a framework. But this argument does not seem to me to be at all conclusive. To my mind it merely proves either (1) that the memories of names are stored up in a special part of the auditory speech centre, while the memories of words other than names are stored up in some other part of the auditory speech centre; or (2) that the memories of words other than names may, perhaps, also be stored in some other centre, possibly in the kinesthetic or vocal speech centre (Broca's centre), as well as in the auditory speech centre. It is quite conceivable that the kinesthetic memories of the parts of speech other than names and attributes may in some cases be so firmly imprinted in the kinesthetic speech centre (i.e., ? Broca's centre or the vocal speech centre) that, after destruction of the auditory speech centre or the part of the auditory speech centre in which the memory pictures of names are stored, they can be independently revived in consciousness and made use of for the purposes of speech and thought.

Various other explanations may also be given. Possibly words other than names—i.e., the parts of speech in which names are set in a framework—which are frequently used are not only imprinted (stored up) in the left but also in the right auditory speech centre. While we must, from the observation of cases of auditory aphasia, suppose that in most persons memory pictures of the objects (nouns) are stored up (or chiefly stored up) in one (the left) auditory speech centre, it is not unreasonable to suppose that the

memory pictures of words representing attributes (adjectives) which are frequently used are bilaterally represented. In health, as everyone knows, it is very common to forget the name of a person; it is much less common to forget the name of a thing or of an action unless that thing or that action is a rare thing or a rare action; it is extremely difficult (almost impossible, I suppose, in health) to forget the name of an attribute (such as *mean* or *good*) which is frequently used and very generally applied; and it is probably still more difficult to forget the words (other than the names of things, actions, and attributes) which form the parts of speech in which names (of things, actions, and attributes) are set in a framework. Exactly the same defects are met with in disease. Names (other than one's own name or the names of one's immediate relatives or of striking personalities such as Bismarck or Gladstone) are first lost. But this does not, to my mind, in any way necessitate the supposition that there is a "naming centre" as distinct from the auditory speech centre. It only shows that the memories of terms and words which are least used are less firmly imprinted (perhaps only imprinted on one side of the brain) and are, therefore, most easily forgotten; whereas the memories of terms and words which are in more constant use are so firmly imprinted and the tracts which connect the cell groups in the auditory speech centre, representing such terms and words, with the associated sensory centre or centres in which are the visual, kinesthetic, or other memories of the objects which those terms or words represent, are so well worn and frequently used that such names and terms are readily recalled and are not easily forgotten.

Again, as Bastian has pointed out, differences in the severity of the lesion, whether it is merely a functional derangement or an organic destruction, will without doubt produce a different effect in the obliteration of the different word memories in accordance with the firmness, so to speak, with which those memories are imprinted or fixed in the cell groups of the auditory speech centre. A comparatively slight functional derangement, which has no effect upon a firmly fixed impression, may obliterate the memory picture of an impression which is less firmly fixed. Faint impressions and faintly fixed impressions tend in the course of time to disappear and the mental pictures which they represent to be forgotten. Faintly fixed impressions will *a fortiori* be easily blotted out either temporarily or permanently by pathological alterations or even physiological changes, such as exhaustion, which either temporarily impair, or permanently destroy, the functional activity of the cell and fibre mechanisms in which they are implanted. It must, however, I think, be admitted that a mere functional degradation of this kind does not satisfactorily account for cases such as Broadbent has described¹²—cases in which the patient is absolutely unable to make use of any name or noun but in which he retains the ability to make use of other parts of speech.

The view which I have just advocated regarding the relationship of the auditory speech centre to the process of thought was clearly expressed by Bastian so long ago as the year 1869 and it is adopted by most authorities. The following extracts from his work on aphasia are, in this connexion, of great importance. In speaking of Broadbent's naming centre he says¹¹:—

It seemed to me wholly unnecessary and at variance with what appeared to be the real nature of the process of perception. . . . Thus the work which Broadbent supposes to be done in his "naming" or "concept" centre is according to my view carried out by the simultaneous activity of the different perceptive centres and certain annexes that are derivative developments therefrom, of which I shall subsequently speak. Again, as I have previously endeavoured to show, perceptive processes vary greatly in complexity and merge by insensible gradations into processes of conception. It seems thoroughly legitimate, therefore, to suppose that these latter more specialised modes of mental activity, whilst having their roots in perceptive centres, may be completed in outgrowths therefrom—that is, in parts of the brain which are in close relation structurally and functionally with the several sensory centres. I have commonly spoken of such regions as "annexes" of the perceptive centres. . . . Those regions seem, therefore, to correspond with what I have referred to above as "annexes of the perceptive centres." They occupy a large proportion of the cerebral cortex and are thus described by Flechsig: (1) in parts of the frontal lobes; (2) in a large portion of the temporal lobes; (3) in a considerable area of the posterior parietal region; and (4) in the island of Reil. These four fairly well defined areas are, as above stated, not directly connected with afferent or with efferent fibres, and, in addition to this, two other regions are given for supporting them to be concerned with the carrying on of higher functions. Flechsig points out, in the first place, that these regions remain immature and completely

¹¹ Brain, vol. I, p. 422.
¹² Aphasia and Other Speech Defects, p. 42, et seq.

devoid of myelins for several months after birth, though the sensorial centres have arrived at comparative maturity; and, secondly, that these association centres are the parts which are especially developed in the brain of man as compared with that of the lower animals." Bastian then points out "that Broadbent had, twenty years previously, cited almost exactly these regions of the cerebral cortex as parts that were neither in direct relation with peduncular fibres nor with those of the corpus callosum and that he had attributed to these regions (for almost exactly similar reasons), just the same functions as those now assigned to them by Flechsig." He adds: "It is, I think, perfectly legitimate to suppose that the annexes of the sensory centres, to which I have previously referred, tend to be developed in the directions above indicated by Broadbent and Flechsig, though how much of these territories they occupy must remain altogether uncertain. It seems also probable that there is no sharp line of demarcation between these annexes and the several sensory areas and that the combined sensory areas, together with the annexes, are accustomed to be thrown into functional activity more or less simultaneously. Thus the processes of perception and conception, together with revival of linguistic symbols, are probably almost as inseparable in their localisation as they are in their nature and modes of occurrence; and their anatomical substrata must be supposed to occupy a very considerable extent of the cortex of both hemispheres." He quotes the late James Ross to the effect: "And on passing from thinking by percepts to thinking by concepts, and from that to thinking by abstracts, there are no new centres introduced, but only a complication upon complication of the one perceptive centre."¹⁵ All that can be said is that the correlative of perceptive thinking is excitation of that portion of the cortex of the brain which is directly connected with the sensory inlets; of conceptive thinking, excitation of portions of the cortex of the brain which are indirectly connected with them; and of abstract thinking, excitation of portions which are still more remotely connected with them. It must, however, be remembered that the effective working of the portions of the cortex which are remotely connected with the sensory inlets will in a great measure depend upon the integrity of those that are in direct relation with them."

In the construction of diagrams illustrative of the higher cerebral and speech mechanisms it is convenient for the sake of simplicity and illustration to introduce above the recognised perceptive or sensory speech centres (auditory speech centre and visual speech centre) and above the motor (or, as Bastian terms them, kinæsthetic) speech centres (vocal speech centre and graphic speech centre) two higher centres representing, on the sensory side, *Consciousness and Intelligence*, and, on the motor side, the *Will*, or one supreme centre representing *Consciousness, Intelligence*, and the *Will*, but it must be remembered that there is absolutely no reason to suppose that any such centres or centre exists as definite and distinct areas or centres in localised parts of the cerebral hemispheres; on the contrary, such a supposition seems to be altogether erroneous and in absolute contra-indication with our knowledge of the working of the brain and of the construction of the nervous mechanisms the integrity of which is essential for the manifestation of the psychical phenomena which we term *Consciousness, Intelligence*, and the *Will*.

All the different areas of the cerebral cortex and their connecting tracts are the physical substrata, the action of which is associated with the psychical or mental phenomena—*Consciousness, Intelligence*, and the *Will*. Each and every one of these cortical mechanisms (centres and associated tracts) forms a part of the physical substrata, the action of which is associated with the manifestation of the psychical phenomena—*Consciousness, Intelligence*, and the *Will*. The cortex as a whole is the seat of *Consciousness, Intelligence*, and the *Will*. Destruction of any one of the sensory or motor (? kinæsthetic) cortical centres necessarily obliterates the memory pictures which are stored up in that centre; the *Intelligence* is thereby the poorer, but in other respects it may remain the same, while *Consciousness* and the *Will* are, or may be, entirely unaffected. In such circumstances, the other mechanisms of the cerebral cortex may continue to play their part, though, in consequence of the loss (obliteration) of the memory pictures which were imprinted in, and the loss of the associations which can only be carried on through, the centre which is destroyed, certain of the faculties of the mind, as an intelligent, thinking, reasoning, and volitional mechanism, must necessarily be to some extent interfered with and impaired.

But while there are no localised centres for *Consciousness, Intelligence*, and the *Will*, and while I see no reason for supposing that there is, as Broadbent thinks, a special naming or idea centre and a special propositionising centre, in addition to the auditory speech centre (which I regard as the naming centre) and the vocal speech centre (which is possibly to some extent a centre in which the memories

of words other than names—the kinæsthetic memories—are stored), it does not, of course, follow that the various sensations and impressions which are primarily represented in the sensory (receptive) centres of the cerebral cortex and which are re-grouped in the higher auditory and visual centres (auditory, visual, and so on) may not be again re-grouped and brought into still more complex relationships in some still higher part of the cerebral cortex; and if this is so, one would naturally expect that the impressions which have been in this way re-arranged, re-grouped, and re-coordinated, as it were, would play (either directly or indirectly) upon the emissive, or, as they are usually termed, motor mechanisms and centres of the Rolandic area (ascending frontal convolution). In other words, it is probable that various sensations and impressions, for the conscious perception of which the sensory centres (auditory, visual, &c.), in the cerebral cortex would alone appear to be sufficient, may be re-grouped and brought into fresh combinations (co-ordination) in some higher and probably adjacent part of the cerebral cortex.

Hughlings Jackson believes that, in addition to the usually recognised motor and sensory centres of the cerebral cortex (which, he thinks, are the second tier of motor and sensory centres, the first or lower tier being in the pons Varolii, medulla oblongata, and spinal cord), there are higher motor and sensory centres. These highest motor centres are, he supposes, situated in the frontal lobes, while the highest sensory centres are, he thinks, situated behind Ferrier's sensory centres. Ferrier thinks such an arrangement unnecessary. But while there may be no sufficient reason for supposing that there are higher centres to which the terms *motor* and *sensory* (in the sense that I understand these terms) can be definitely applied, it is quite reasonable, I think, to suppose that there are higher centres in which the conscious impressions which have been registered and retained in the lower (ordinary) sensory centres of the cerebral cortex and which have been re-arranged and re-coordinated (in order that they may be brought into anatomical and physiological connexion with other and more distinct centres) in such centres as the auditory speech centre, the higher visual centre and their "annexes," may be again gathered together, as it were, re-arranged and co-ordinated in a still more complex and intricate manner. If these highest centres exist, they are perhaps situated in the prefrontal lobes, which are very generally regarded as being in a special sense the seat of the intelligence and of attention—as centres placed, as it were, above all the other centres and parts of the brain. Some such mechanism would appear necessary to form the physical substrata associated with the more complex mental processes of abstract thinking, deliberation, volitional attention, and the like; and this, I think, be allowed to be an argument in favour of the supposed existence of such highest centres. But when we grant that, we perhaps grant all. In the present position of our knowledge the question must necessarily be left an open one.

But even if such highest centres exist, they cannot, of course, be regarded as the exclusive seat of *Consciousness, Intelligence*, and the *Will*; they can only be regarded as the position in which the nervous mechanisms of lower sensory and motor centres (and their annexes) in the cerebral cortex are re-coordinated and re-combined and brought into relationship so as to facilitate the complex mental process of abstract thinking, deliberation, judgment, control, and the like.

THE PHYSICAL BASIS OF MEMORY.

In this and the preceding lecture I have more than once spoken of mental pictures or memory pictures being stored in particular cell groups of the cerebral cortex. These statements are not, of course, strictly accurate. Mental pictures and memories are psychical phenomena; they consequently cannot be stored up in nerve cells; they—the psychical phenomena—occur in connexion with certain physical changes in the nerve cells of the cortex and although everything that we know of the working of the brain seems to show that the physical (nervous) changes are necessary and essential for the production of the psychical phenomena which attend and are developed coincidentally with the nervous (physical) changes, the one (the psychical) cannot be expressed in the terms of the other (the physical). The two sets of phenomena though concurrently manifested are, so far as our present knowledge enables us to judge, totally and radically different and distinct. Further, it must be remembered that, although the revival of a particular

¹⁵ It would be more correct, I think, to say that in passing from thinking by percepts to thinking by concepts and from that to thinking by abstracts the same centres are engaged and that there is merely a complication upon complication of the different perceptive centres and their annexes which are scattered through the cerebral cortex.

mental picture or idea necessitates the re-stimulation or re-excitation of exactly the same nerve elements, which were stimulated and excited when the mental picture or idea was originally (i.e., first) perceived in consciousness, and that a particular mental picture can only be revived as the result of the re-stimulation and re-excitation of those nerve elements and of *no others*, the mere re-stimulation and re-excitation of those nerve elements does not express the whole nervous change which corresponds to the revival in consciousness of the *memory* of that idea. In order that the re-excited image may be perceived in consciousness as a *memory*, consciousness must be aware of the fact that the idea has been perceived before; consequently a something more in the way of nerve change than the mere revival of the idea is obviously necessary. That this is so is proved by the fact that when the memory of an idea is completely lost the re-stimulation and re-excitation of the nervous elements (which form the anatomical and physiological substratum of that idea) merely excite and raise up in the mind the primary idea and not the memory of that idea. I see, for example, an object—say, a particular man; his is attended with the stimulation of a certain group of nerve cells in the visual centre. The fact that I have seen the individual fades from the mind, the memory is lost. But when the object is again presented to me—when I again see the same man—the same group of nerve cells is again stimulated; but the additional something in consciousness (the “*setting*” of the mental picture or idea, as W. James terms it) has been lost, the nerve change, whatever it is, which is attended with the development in consciousness of the *additional something* is not excited and I say I have never seen that man before. What this additional nerve change, which is attended with the consciousness of the fact that the mental picture or idea has been perceived before, is we do not (so far as I am aware) exactly know, but there seems every reason to believe that it must consist in an overflow from the cell group in which the original mental picture is stored to some associated cell group or cell groups, and the raising up in the mind, in consciousness, of a something which was (perhaps with the revival of the mental ideas which were) coincidentally aroused when the mental picture was originally perceived in consciousness.¹⁶

¹⁶ James puts it in the following terms: “Memory requires more than mere dating of a fact in the past. It must be dated in *its part*. In other words, I must think that I directly experienced its occurrence. It must have that ‘warmth and intimacy’ which were so often spoken of in the chapter on the Self as characterizing all experiences ‘appropriated’ by the thinker as his own. A general feeling of the past direction in time then, a particular date conceived as living along that direction, and defined by its name or phenomenal contents, an event imagined as located therein, and owned as part of my experience—such are the elements of every act of memory. It follows that what we began by calling the ‘image’ or ‘copy’ of the fact in the mind is really not there at all in that simple shape as a separate ‘idea.’ Or at least, if it be there as a separate idea, no memory will go with it. What memory goes with is, on the contrary, a very complex representation, that of the fact to be recalled plus its associates, the whole forming one ‘object,’ known in one integral pulse of consciousness, and demanding probably a vastly more intricate brain-process than that on which any simple sensorial image depends. A simple scheme (see Fig. 17) will now make the whole cause of memory plain. Let: n be a

FIG. 17.

part event: a life-setting (concomitant, date, and present, warmth and intimacy, &c., &c., as already set forth); and in some present thought or fact which may appropriately become the occasion of its recall. Let by M, N, and O respectively, then the existence of the paths M-N and N-O will be the fact indicated by the phrase ‘recollection of the event’ in the memory, and the connection of the brain along these paths will be the condition of the event as actual recall. The *re-stimulation* will be observed, as an external arising up of an ‘idea’ in its unconscious state. It is not a fact of the mental order at all. It is a purely physical phenomenon, a morphological feature, the presence of

Lecture

ON

THE ETHICS OF THE MEDICAL PROFESSION IN RELATION TO SYPHILIS AND GONORRHOEA.

Delivered before the Harreian Society on Feb. 8th, 1906.

By CAMPBELL WILLIAMS, F.R.C.S. Eng.

GENTLEMEN,—It has always appeared to me to be more than passing strange that the laws of our country whilst making it incumbent upon the medical profession to notify the public health authorities of the existence, and consequently the likelihood of propagation, of certain duly specified diseases, either of a contagious or infectious nature, have nevertheless apparently deemed it unnecessary, or perchance impolitic, to include that health-ruining and race-deteriorating malady syphilis within their schedule. One can better understand the omission of gonorrhoea from the catalogue, since the average lay mind fails to grasp the gravity of its possibilities and fallaciously relegates it to the domains of trivial complaints.

There is probably no medical man who has not on many occasions been brought face to face with patients of both sexes suffering from one of the many disastrous results to which the intruding and aggressive gonococcus may give rise—effects which may not only ruin happiness and health for good and all but maybe lead to death. With syphilis, however, one would think that the plea of ignorance as to its baneful capabilities could never have been a factor which influenced its exclusion from any list of public dangers. One must rather attribute its omission to that false sense of modesty which pervades the average British mind and prevents public reference or consideration of any disease in connexion with the “to silence sacred” genital organs. It would seem that though we are cognisant of an existing and ubiquitous danger we nevertheless prefer, through lack of moral courage, to close the legislative eye and to remain sanitariously dumb upon a subject and condition of affairs which is medically admitted to be one that demands the State’s most urgent attention. The position of any medical man, and more particularly the family medical adviser, when he has learned of the existence of gonorrhoea or active syphilis in one member of a married couple is under the present régime, which imposes the toils of quasi-father confessorship upon us, not a particularly enviable one. For though fully recognising the possible—nay, even probable—danger of propagation, one is in many instances closely restricted to giving the patient a solemn warning as to the intense contagiousness of the disease and to dilating upon the certainty of its dissemination should our admonition, as it too often is, be disregarded. We are, so to speak, tongue-tied and have, through professionally enforced silence, to rely against further propagation of infection upon the dictates of a conscience which has already proved itself unworthy of trust. If this were not so we could often be in time, by calling a spade a spade, to safeguard the innocent against contagion and the misdeed of adultery, culminating in gonorrhoea or syphilis, would not have to be temporarily screened by those whose duty it should be to preserve health. I have no doubt that the cost of this quarantine, which is denied us, would be either a voluntary or judicial separation, but perchance with a woman’s health preserved. For in the large bulk of cases of domestic venereal disorders it is the man who propagates disease through having consorted with some infectious prostitute. It may be that some wives would not agree with me when I say that were I but a woman I should consider freedom from syphilis or Fallopian tube mischief to be cheap even

these ‘paths,’ namely, in the direct recesses of the brain’s tissue. The recall or recollection, on the other hand, is a psychophysical phenomenon, with both a bodily and a mental side. The bodily side is the functional excitement of the tracts and paths in question; the mental side is the conscious vision of the past occurrence and the belief that we experienced it before.” (The Principles of Psychology, vol. I, pp. 650, 651, and 652.)

at the price of marital separation and to be infinitely preferable to impaired health and possibly subsequent divorce proceedings on the grounds of "adultery and legal cruelty." But the restraint which our cloth imposes upon us, that secrecy and confidential relationship which exists between medical man and patient, not only ties the mouth but compels us, until the law wills otherwise, to confine our well-meant timely warning, so pregnant with danger to an innocent and unsuspecting woman, to some fairy tale or else cryptic hints which as often as not fall upon the wifely ear as empty meaningless words. It has always seemed to me to be somewhat of a paradox that whilst one may unhesitatingly appraise a man's wife of the existence of some trifling exanthem within her home and against which she may be immune, we are nevertheless in certain instances bound to exercise an almost criminal reticence towards her—a conspiracy of silence as it were—when dealing with venereal diseases which in all probability may gravely concern her future health and welfare. It is needless for me to point out that when infection has, or probably has, been effected one could serve no good purpose by enlightening an unsuspecting wife as to the true nature or cause of the illness from which she is suffering. Moreover, she would probably not understand the bald mention of such diseases as syphilis or gonorrhoea. It would require a full and lucid explanation to make her realise the contingencies necessary for their contraction and dissemination. In such a case ignorance is bliss, more particularly when she perchance idolises her husband and regards him as an impervious monument of morality. Any awakening as to marital deception would do no good but only add unhappiness to ill-health.

Let us now consider the somewhat awkward position of a practitioner who has been called in to see some ailing servant, such as a parlour-maid, cook, or even nursemaid who bathes, clothes, and feeds the children of the house, perchance putting the very spoon with which they eat into her mouth. He may find the patient, as I have done, to be rampantly syphilitic or else gonorrhoeally infected, exuding drachms of most contagious pus daily, and consequently a possible danger to every other member of the household. In such cases there can be, in my opinion, no alternative judgment or course. The patient must leave her situation at once, either voluntarily or, if needs be, through pressure or even exposure. Perhaps there may be some sticklers of ethics who would not agree with me as to the permissibility of disclosure, even in such a flagrant case, should such a drastic course become actually necessary to make her go. But I feel convinced that most people would more than thank me for my breach of faith on behalf of their safety. The more perplexing cases as to what is the right thing to do are those in which an element of doubt is present. The patient is suffering from a hitherto unknown *anæmia* and lassitude and complains of being feverish towards and during night-time, but which symptom has left her, so she says, when she wakes in the morning. You know that she has recently been immoral, because she has confessed as much to you, and consequently you may think of syphilis as a possible cause for these symptoms. An examination, if such be permitted, reveals no unimpeachable signs of the malady and though you may shrewdly suspect the disease to be the "*fons et origo mali*" you are for the time being uncertain as to its presence or not. I think we would all agree that you could not inform her mistress of the immorality—a fact which you have gleaned as it were under the seal of confession—and you could not hint about the doubts which fill your mind as to the possible nature of the disease without thereby disclosing the exciting cause thereof. In one hand you hold the patient's confidence and in the other the safety maybe of a third person, and you are bound to respect both. Well, I am afraid that all which one can do is to wait and watch, taking upon your own shoulders any and all risks which your professional silence engenders. Fortunately for us, cases of infection in this wise—that is, mediate communication—are comparatively rare. But they do occur from time to time, as many of us have experienced. Of course, in the case of a vaginal discharge any element of doubt as to its gonorrhoeal or leucorrhoeal nature can be quickly dissipated by microscopical examination. This should never be neglected, since acute or even subacute leucorrhoea so often mimics many of the classical symptoms of its venereally contracted and ophthalmically dangerous prototype. With suspected syphilis, however, I do not think that the microscopical discovery of a spirochæta in the

blood would make most of us unhesitatingly plump for the existence of that disease, in the absence of all outward and visible signs of the malady, other than the prodromal symptoms. Personally, in such a case I should feel inclined to throw the odium of a possibly incorrect diagnosis on a professional pathologist, or, at least, until we have more unequivocal proof that the presence of the spirochæta is "the cause" of the syphilitic phenomena, though I must say that I think Schaudinn and Hoffmann are right and that they have discovered the organism. Possibly the spirochæta pallida may open up a new line of treatment.

In consulting practice one's patients are frequently, if I may use the term, but perambulating units of suffering humanity. One neither knows who they are or whence they come, and once they have re-crossed the threshold of your doorstep they go forth to mix amongst their fellow creatures free from all restraint excepting such as your warning and the dictates of their own conscience may impose upon them, both of which influences are but slender reeds which either the swish or rustle of a passing petticoat may swiftly bow to earth and thereby perpetuate the cycle of disease. There is a good old saying that "half a loaf is better than no bread." So if the State cannot, for politico reasons, make the notification of the diseases in question applicable to society at large it might at least take steps to enforce restraint upon that abandoned element of the population which gains its livelihood through vice. The prostitute is undoubtedly the fountain head for the propagation of these diseases. I take it that if one wishes completely to rid a view of an unsightly tree, or a field of some rank evil-spreading weed, the quickest way to attain that end is not to lop off branches here and there but to try to uproot it in its entirety. But what is the position or attitude of the medical profession in this matter? It is simply one of helplessness, if not carelessness. One may see a prostitute plying for hire, either in the streets or else in some place of amusement whom only a few hours ago you have examined and found to be syphilitic, and who, notwithstanding all your warnings which have scarcely had time to grow cold, cannot, under our present laws, be restrained from infecting the community. This seething mass of syphilis is absolutely free to do as she lists. If any medical man doubts the accuracy of this statement, which I make through many years' experience at the Lock Hospital, I would advise him to apply for permission to attend the female out-patient department of such an institution and on that selfsame night to go out either into the highways or else to some place of amusement which this class of women frequent, and put his memory of faces to the test. I feel more than convinced that an extra strong wave of morality would sweep over him, and that he would thereafter see the position of affairs from the sanitary point of view to which I wish to draw your attention. No amount of legislation other than the drastically lethal method employed by certain native races will make a nation or people as a whole moral and since we cannot attain that most desirable end surely the next best thing to do is to make some earnest endeavour to preserve the community's health. I think it is a pretty well recognised fact that many people contract venereal disease not through erring with malice aforethought but through being waylaid by some perambulating prostitute who happens to accost them in a weak moment when alcohol has capsize their better judgment and made them cast all thought of consequences, assuming that they ever knew of the existence of such, to the four winds of heaven. Many a married workman with his week's wages in his pocket and a little Saturday afternoon drink within his stomach would have reached his home and wife safely and undiseased if our streets were but free from such limpet-like pests. Nor would the silly youth who happens to have taken more wine than his weak head and erotic centres would stand be lured for the first time in his life to whoredom and disease through accidentally meeting some importuning and infectious harpy. Many of these boys—for they are little better than that—even if they chanced to know the whereabouts of a brothel would, through never having been to one before, lack sufficient courage to go there but would reach home possibly sick at stomach but otherwise sound in body and health.

Now here are we medical men, who as a party should be some 30,000 strong, content as it were with this attitude of *laissez faire*. A few individuals here and there may raise the voice of protest but as a body corporate, thousands of whose unsuspecting fingers have been syphilitically infected in the discharge of their professic

discreetly dumb, at least negligently silent upon this urgent matter, allowing our knowledge and experience to be overruled and stultified by the judgment of certain people who are totally unqualified by aught than fanaticism to express an opinion on such a momentous matter—a subject of which they have neither medical knowledge nor practical experience. There is a certain section of this class who, either from a strong religious or extra-moral sense of duty, hold that any preventive measure which might confer a degree or element of safety upon vice is consequently wrong. They fallaciously seem to think, though their thoughts are contrary to the weighty evidence of facts, that the terror of contracting disease will act as a deterrent to fornication and that fear is either conducive to, or will generate, morality in a nation. Their dictum would appear to be allied to that Gilbertian one which holds that the "punishment should fit the crime," apparently oblivious or heedless of the fact that the innocent too frequently share the penalty with the guilty and oft-times endure the bulk of it. To my mind there is no reason why the sins of the fathers should be visited upon the wives, much less the children. We could and should stop both to a very large degree. I have often wondered if some of these hysterical and narrow-minded champions of "morality at any price" were to become accidentally infected whether they would subsequently hold their same intolerant views or if they would not, even more than ordinary people, resent the supineness of our laws which permit the uncontrolled transmission of those diseases which they themselves strive so hard to perpetuate. My experience of this class is that they regard the safety of their own skins from a very different standpoint to that from which they view other people's and are amongst the loudest with their shrieks should danger draw unpleasantly near themselves. We as medical men, even though we do not express our views with the vehemence of an Exeter Hall orator, may perchance realise, just as clearly as the laity, clergy, or even elderly spinsters, that immorality is neither good for the individual nor for the community at large. But as men of the world we are broad-minded enough to recognise the patent fact that no effort on our part will alter human nature as it is and as it ever seems likely to be. *Naturam furcæ expellas tamen usque recurret.* For natural passions always have found, and always will continue somehow to find, their vent, and no amount of preaching on our or anybody else's part will alter the trend of humanity.

The present-day cost of maintaining a wife is more than frequently a financial bar to many a young man who would otherwise seek and find sanitary salvation in matrimony. But as want of means denies him this luxury it too often happens that his natural erotic tendencies lead him within that zone of dangers which ever beset indiscriminate intercourse, even if they do not cast him upon the lurking rocks of syphilis or gonorrhoea. Everybody is not built with a stable nervous organisation or with a strong will-power. Nor is the trend of their heritage calculated to enhance the spontaneous growth of a morality the principles of which have never been properly inculcated within the childish or youthful breast by parental tuition, advice, or example. With many people immorality deserves pity rather than blame in that it is a symptom of inherited psychical degeneration just as much as dipsomania, crankishness, and any blatant anti-socialism which often are but other phases by which ancestral neuroses declare themselves. The narrow borderline between genius and insanity not infrequently expresses its existence by either an irresistible or else a perverted erotism. Some people are moral, I might say truly moral, purely from their parental training and upbringing which have developed within them a higher sense of right and wrong. Others inherit morality through that pure accident of birth which finds them, through either an arrested development of the cerebral sexual centres or from a faulty growth of the genital apparatus, with an almost total absence of sexual instinct or desire. This piece of luck, if such it be, endows them with an unearned and ready-made cloak of righteousness which they seem to love to flaunt as an example to the weaker members of the community. To them immorality, and not morality, would be the effort. A few of those who pose as moral towards the female sex owe the attainment of their power for celibacy, as they have confessed to me, to self-engendered conditions which would hardly meet with approval, nor could the practice by which their revelation or impotence is gained be recommended as a panacea or substitute for sexual

intercourse. In fact, I question whether the secret and vicious cause for their ostensible morality is not a greater evil to body and mind than fornication itself. In my experience it is often much more difficult to rehabilitate lost manhood, or to relieve some of its more distressing symptoms than it is to cure an average case of syphilis. Many of these poor weak-minded wights in their secret endeavours to assuage nature and to avoid disease have wrecked their lives and health just as badly as the infected and fornicating impotent libertine. It is not any of these types of moralist who require our protection against venereal disease, in that they, after their own particular fashion, protect themselves; it is rather the medical profession which requires shielding from their well-meant but misguided efforts which have done so much to counteract all our attempts towards restricting disease.

I must now bring this plain-speaking paper to an end and I would ask your kind consideration and opinion upon the following controversial points. Shall we knowingly and wittingly permit diseases which we could, and in my opinion should, check from exercising their baneful results without any effort on our part to restrain their dissemination? Or should we as a profession awake from our lethargy and by showing a united front make some endeavour to arrest their spread and ravages. Moreover, are we justified in certain cases in relaxing our attitude of professional secrecy and reticence when we have good reason for believing that our sphinx-like demeanour will probably result in some innocent person being infected; or shall we, like Nero whilst Rome blazed, be callous of a woman's health which may perchance, through our silence, be scathed or even burned to cinders of its former self? I take it that in this game of Human Bridge, of which the stakes are health, we as a profession not only hold four aces and all the leading cards but likewise have the "call."

SOME OBSERVATIONS UPON THE ETIOLOGY OF OBLIQUE INGUINAL HERNIA.

BY R. W. MURRAY, F.R.C.S. ENG.,

Surgeon, David Lewis Northern Hospital, Liverpool.

THAT there should be some considerable doubt as to the etiology of such a common complaint as inguinal hernia does not reflect much credit upon the medical profession, and I trust, in view of the numerous contributions to the literature of this subject by many illustrious surgeons, that the following remarks of an obscure provincial surgeon who certainly lays no claim to originality may not be considered an impertinence.

Though the presence of an inguinal hernia must be due to some weakness of the structures which form the opening through which the abdominal contents escape, the question yet to be answered is, What are the chief factors which constitute this weakness and so determine the descent of the bowel? It is, I believe, generally admitted that in the great majority of such herniæ which occur during infancy the local weakness is due to the presence of a pre-formed sac, an unobliterated portion of the processus vaginalis testis. In the ordinary hernia of adult life, however, the local weakness is not as a rule considered to be due to any such congenital defect but to be confined to the muscular and aponeurotic structures of the abdominal wall which permit of the escape of the bowel by pushing the parietal peritoneum in front of it. This division of herniæ into "congenital" and "acquired" has of recent years been severely criticised, more especially by Mr. R. Hamilton Russell of Melbourne who adduces evidence in favour of the belief that the presence of a pre-formed sac is the main factor in the causation of hernia during all periods of life.

Before offering any theoretical explanations concerning the conditions which predispose to the formation of a hernia it will be well to reconsider certain ascertained facts. It is only by dealing with a large number of cases that one is able to learn not only what is the usual type of hernia but also the different periods of life at which hernia most commonly occurs. Thanks to the labours of Mr. J. F. C. H. Macready, we have in his classical work, "A Treatise on Ruptures," these necessary facts before us. Mr. Macready's table of statistics comprises 20,999 cases of hernia occurring in

at the price of marital separation and to be infinitely preferable to impaired health and possibly subsequent divorce proceedings on the grounds of "adultery and legal cruelty." But the restraint which our cloth imposes upon us, that secrecy and confidential relationship which exists between medical man and patient, not only ties the mouth but compels us, until the law wills otherwise, to confine our well-meant timely warning, so pregnant with danger to an innocent and unsuspecting woman, to some fairy tale or else cryptic hints which as often as not fall upon the wifely ear as empty meaningless words. It has always seemed to me to be somewhat of a paradox that whilst one may unhesitatingly apprise a man's wife of the existence of some trifling exanthem within her home and against which she may be immune, we are nevertheless in certain instances bound to exercise an almost criminal reticence towards her—a conspiracy of silence as it were—when dealing with venereal diseases which in all probability may gravely concern her future health and welfare. It is needless for me to point out that when infection has, or probably has, been effected one could serve no good purpose by enlightening an unsuspecting wife as to the true nature or cause of the illness from which she is suffering. Moreover, she would probably not understand the bald mention of such diseases as syphilis or gonorrhoea. It would require a full and lucid explanation to make her realise the contingencies necessary for their contraction and dissemination. In such a case ignorance is bliss, more particularly when she perchance idolises her husband and regards him as an impervious monument of morality. Any awakening as to marital deception would do no good but only add unhappiness to ill-health.

Let us now consider the somewhat awkward position of a practitioner who has been called in to see some ailing servant, such as a parlour-maid, cook, or even nursemaid who bathes, clothes, and feeds the children of the house, perchance putting the very spoon with which they eat into her mouth. He may find the patient, as I have done, to be rampantly syphilitic or else gonorrhoeally infected, exuding drachms of most contagious pus daily, and consequently a possible danger to every other member of the household. In such cases there can be, in my opinion, no alternative judgment or course. The patient must leave her situation at once, either voluntarily or, if needs be, through pressure or even exposure. Perhaps there may be some sticklers of ethics who would not agree with me as to the permissibility of disclosure, even in such a flagrant case, should such a drastic course become actually necessary to make her go. But I feel convinced that most people would more than thank me for my breach of faith on behalf of their safety. The more perplexing cases as to what is the right thing to do are those in which an element of doubt is present. The patient is suffering from a hitherto unknown anaemia and lassitude and complains of being feverish towards and during night-time, but which symptom has left her, so she says, when she wakes in the morning. You know that she has recently been immoral, because she has confessed as much to you, and consequently you may think of syphilis as a possible cause for these symptoms. An examination, if such be permitted, reveals no unimpeachable signs of the malady and though you may shrewdly suspect the disease to be the "fons et origo mali" you are for the time being uncertain as to its presence or not. I think we would all agree that you could not inform her mistress of the immorality—a fact which you have gleaned as it were under the seal of confession—and you could not hint about the doubts which fill your mind as to the possible nature of the disease without thereby disclosing the exciting cause thereof. In one hand you hold the patient's confidence and in the other the safety maybe of a third person, and you are bound to respect both. Well, I am afraid that all which one can do is to wait and watch, taking upon your own shoulders any and all risks which your professional silence engenders. Fortunate for us, cases of infection in this wise—that is, mediate communication—are comparatively rare. But they do occur from time to time, as many of us have experienced. Of course, in the case of a vaginal discharge any element of doubt as to its gonorrhoeal or leucorrhoeal nature can be quickly dissipated by microscopical examination. This should never be neglected, since acute or even subacute leucorrhoea so often mimics many of the classical symptoms of its venereally contracted and ophthalmically dangerous prototype. With suspected syphilis, however, I do not think that the microscopical discovery of a spirochæta in the

blood would make most of us unhesitatingly plump for the existence of that disease, in the absence of all outward and visible signs of the malady, other than the prodromal symptoms. Personally, in such a case I should feel inclined to throw the odium of a possibly incorrect diagnosis on a professional pathologist, or, at least, until we have more unequivocal proof that the presence of the spirochæta is "the cause" of the syphilitic phenomena, though I must say that I think Schaudinn and Hoffmann are right and that they have discovered the organism. Possibly the spirochæta pallida may open up a new line of treatment.

In consulting practice one's patients are frequently, if I may use the term, but perambulating units of suffering humanity. One neither knows who they are or whence they come, and once they have re-crossed the threshold of your doorstep they go forth to mix amongst their fellow creatures free from all restraint excepting such as your warning and the dictates of their own conscience may impose upon them, both of which influences are but slender reeds which either the swish or rustle of a passing petticoat may swiftly bow to earth and thereby perpetuate the cycle of disease. There is a good old saying that "half a loaf is better than no bread." So if the State cannot, for politic reasons, make the notification of the diseases in question applicable to society at large it might at least take steps to enforce restraint upon that abandoned element of the population which gains its livelihood through vice. The prostitute is undoubtedly the fountain head for the propagation of these diseases. I take it that if one wishes completely to rid a view of an unsightly tree, or a field of some rank evil-spreading weed, the quickest way to attain that end is not to lop off branches here and there but to try to uproot it in its entirety. But what is the position or attitude of the medical profession in this matter? It is simply one of helplessness, if not carelessness. One may see a prostitute plying for hire, either in the streets or else in some place of amusement whom only a few hours ago you have examined and found to be syphilitic, and who, notwithstanding all your warnings which have scarcely had time to grow cold, cannot, under our present laws, be restrained from infecting the community. I feel more than convinced that an extra strong wave of morality would sweep over him, and that he would thereafter see the position of affairs from the sanitary point of view to which I wish to draw your attention. No amount of legislation other than the drastically lethal method employed by certain native races will make a nation or people as a whole moral and since we cannot attain that most desirable end surely the next best thing to do is to make some earnest endeavour to preserve the community's health. I think it is a pretty well recognised fact that many people contract venereal disease not through erring with malice aforethought but through being waylaid by some perambulating prostitute who happens to accost them in a weak moment when alcohol has capsized their better judgment and made them cast all thought of consequences, assuming that they ever knew of the existence of such, to the four winds of heaven. Many a married workman with his week's wages in his pocket and a little Saturday afternoon drink within his stomach would have reached his home and wife safely and undiseased if our streets were but free from such limpet-like pests. Nor would the silly youth who happens to have taken more wine than his weak head and erotic centres would stand be lured for the first time in his life to whoredom and disease through accidentally meeting some importuning and infectious harpy. Many of these boys—for they are little better than that—even if they chanced to know the whereabouts of a brothel would, through never having been to one before, lack sufficient courage to go there but would reach home possibly sick at stomach but otherwise sound in body and health.

Now here are we medical men, who as a party should be some 30,000 strong, content as it were with this attitude of *laissez faire*. A few individuals here and there may raise the voice of protest but as a body corporate, thousands of whose unsuspecting fingers have been syphilitically infected in the discharge of their professional duties, we remain, if not

other hand, the opening is large and the inguinal sphincter weak, the probabilities of a hernia occurring are considerable. The frequent occurrence of inguinal hernia in infants would thus be explained.

The frequency with which hernia first appears about the age of puberty I would explain by the increased amount of exercise usually indulged in at this period, and so the muscles which under ordinary conditions are able safely to guard a patent internal opening are suddenly overtaxed and the bowel escapes. This will, of course, largely depend upon the size of the internal opening. In the case of a hernia appearing later in life the same reasoning would hold good. Though the processus vaginalis has been to some extent patent since birth, no hernia has appeared, for the internal opening was never large and the sphincter was well able to guard it, but with declining years and weakened muscles the sphincter at some critical moment fails and the bowel or omentum passes through. Hernia not infrequently makes its first appearance during convalescence from a long illness. Under these conditions it appears to me more reasonable to explain such an occurrence in the way I have endeavoured to rather than to suppose such a hernia to have been acquired.

If this explanation of the etiology of hernia is correct it clearly has some important bearing upon our methods of curing it, for our chief objects in operating should be completely to do away with any semblance of an internal opening or depression and at the same time to preserve the inguinal sphincter intact. Other things being equal, the operation should be performed very early in life so as to make sure that the funicular process is really closed and also to prevent subsequent weakening of the muscles guarding the opening from the descent of the bowel constantly stretching them.

Note.—Since writing this paper I have obtained some most interesting and valuable information, owing to the courtesy of my friend, Dr. Nathan Raw, physician to the Mill-road Infirmary, Liverpool, and the kind interest taken in the matter by Dr. R. A. Macleod, Dr. B. G. Wills, and Dr. Arthur Hendry, the resident medical officers. In 100 consecutive and in no way selected post-mortem examinations made at the Mill-road Infirmary, Liverpool, upon persons in whom during life there was no history or evidence of hernia, a potential hernia sac was discovered in the following 21 cases. The number of cases examined was 100—61 males and 39 females.

No. of case.	Age (Years).	Sex.	Potential hernia sac.
1	43	Male.	Double inguinal and right femoral.
2	61	"	Double inguinal.
3	45	"	Left femoral.
4	57	"	Right femoral.
5	39	"	Right inguinal (contained piece of omentum).
6	55	"	Left inguinal (contained piece of omentum).
7	42	"	Left femoral.
8	29	"	Right femoral.
9	44	"	Double inguinal and double femoral.
10	30	"	Right and left femoral.
11	63	"	"
12	62	"	Right femoral.
13	32	"	Left inguinal.
14	40	Female.	Right femoral.
15	14	"	Right and left femoral.
16	62	"	Left femoral.
17	54	"	Right femoral.
18	32	"	"
19	60	"	Right and left femoral.
20	47	"	Left femoral (contained piece of omentum).
21	56	"	Umbilical (contained piece of omentum).

In most of the cases the unobliterated portion of the processus vaginalis testis was about one inch in length and the opening at the internal abdominal ring was so narrow as barely to admit a large probe. In others the opening was sufficiently large to admit the little finger, and in three of

the cases the sac contained a small piece of omentum, which was not adherent and was readily withdrawn. In seven instances more than one sac was found and in Case 9 it will be noticed that an inguinal and a femoral sac existed on either side. In no case was an obturator or sciatic sac present.

Though the number of cases here dealt with is far too small to furnish any accurate information respecting the relative frequency with which a potential hernia sac may occur among persons in whom during life there is no evidence of a hernia (the proportion in this series being probably exceptionally high) still these cases certainly go a long way, if not the whole way, to prove the truth of Mr. Hamilton Russell's contention, that in all ordinary inguinal and femoral hernias the sac is pre-formed and of congenital origin.

Liverpool.

FATAL RUPTURE OF A PYOSALPINX DURING LABOUR.

By J. W. ROB, M.D. CANTAB.

THE following case is interesting in more ways than one. It is not often that an undiagnosed pyosalpinx ruptures during labour. The symptoms manifested were not those usually presented by cases of ruptured pyosalpinx. And the case shows how a medical man may, through no fault of his own, be involved in troublesome and painful circumstances against which he could not possibly have guarded.

On Wednesday, Dec. 6th, at 8.30 P.M. I was called to a woman in labour. My partner had died only two days previously and he had promised to attend the case. The woman, whom I saw for the first time that evening, was apparently strong and healthy. She had been married ten months. A monthly nurse was in attendance. I was told that labour began on Monday morning about 5 A.M. and that the membranes ruptured about noon the same day. Pains had been strong and frequent on Tuesday and nothing abnormal had been noticed. Nourishment was taken well on Monday and Tuesday. The woman had no sleep on Tuesday night. The nurse said that she had not sent for me before because she knew that the first labour was often a long one. At 8.45 P.M. on Wednesday the woman was pale and exhausted; her temperature was 98° F. and her pulse was 120 per minute. The presentation was left occipito-anterior and the head was engaged in the brim of the pelvis. The os was fully dilated. Between 8.45 and 9.30 P.M. there were four or five feeble pains which had no effect in moving the head so I sent for assistance and, chloroform having been given, delivered a healthy male child with forceps without any more trouble than a slight rupture of the perineum which was sewn up at once. Previously to the administration of chloroform the abdomen was quite soft and not tender. There had been no vomiting. The uterus contracted well and the placenta and membranes came away entire. A douche of 1 in 2000 perchloride of mercury was given. At 11.30 P.M. the patient had recovered from the anæsthetic and was quite comfortable and in very good condition.

On Thursday both mother and child were doing well. The mother had not been sick since midnight, had taken two pints of hot milk and some beef-tea, and had no abdominal pain or tenderness. The temperature was 99° and the pulse was 88. The baby had a large caput succedaneum but otherwise was very well. On Friday morning at 11 o'clock I saw the mother again. She had had a comfortable night but had vomited once at 10.30 A.M. and had also had a large very loose action of the bowels at the same time. The abdomen was not rigid or distended or tender and the uterus could easily be felt. The temperature was 100° and the pulse was 96. The child was crying a good deal and as this seemed to annoy the mother he was taken into another room. At 4.30 P.M. I saw the mother again. She had vomited twice since noon and the bowels had been opened four times. There was some pain of a colicky nature in the abdomen but there was no rigidity or distension and the uterus was easily felt. There was no tenderness in the abdomen. The tongue was clean and moist. Nothing abnormal could be detected in the thorax. The temperature was 99.6° and the pulse was 96. I gave a quarter of a grain of morphine tartar hypodermically and ordered a dessertspoonful of hot water

persons of all ages. An examination of these tables reveals the following facts. "Hernia may appear for the first time at any age but the greatest number of herniæ are developed during the most active period of life and age lessens their frequency. In the first year of life a larger proportion of persons are ruptured than in any subsequent year. A large increase in the production of hernia occurs in males between the ages of 11 and 15 and in females between the ages of 16 and 20. The surprising frequency of male inguinal hernia, which occurs nearly six times as often as the other divisions taken together." In 100 men ruptured 97.5 have inguinal hernia and 2.5 have femoral hernia. Among 100 women ruptured 60.3 have inguinal hernia and 39.7 have femoral hernia. "Inguinal hernia occurs with greater frequency on the right than on the left side throughout all periods of life, though this is slightly more markedly so in men than in women."

Let us now consider the distinction between the pre-formed and the ordinary sac of an inguinal hernia as seen at an operation. I believe most surgeons will agree with the following remarks which I quote from Mr. Macready's work: "It is not always possible to distinguish from one another, either in the living or in the dead, the two classes of sacs, and therefore much which has been observed and written of hernial sacs applies to them indifferently, without regard to their mode of origin."

When an inguinal hernia appears during infancy or early childhood the sac is generally regarded as being of congenital origin but when the hernia appears for the first time during adult life the sac is usually considered to have been acquired. Before attempting to differentiate between the two forms of sac in the inguinal region it will be advisable to study the formation and structure of a typically congenital and a typically acquired sac in order to compare them and clearly to understand in what respect they resemble or differ one from the other. For this purpose we will compare the sac of a hernia which we know to have been acquired with the sac of one which we know to have been pre-formed. In the case of a ventral hernia, such as is occasionally seen after laparotomy, which beyond dispute is an acquired hernia, the weakened structures of the abdominal wall corresponding to the line of incision gradually yield, a general bulging takes place, and the parietal peritoneum protrudes, stretching the cicatrix over it. At the point where the bowel has escaped through the abdominal wall the muscles and aponeurosis are atrophied, the mouth of the sac is wide, it has no neck, and consequently strangulation of its contents very seldom occurs. When, on the other hand, the bowel or omentum passes through the external abdominal ring into a sac formed by the tunica vaginalis such a sac was obviously pre-formed and of congenital origin. The neck of the sac is long and narrow which accounts for the frequency with which strangulation of the contents occurs. In a congenital hernia the different parts of the sac can be readily differentiated into the mouth, the neck, and the body but in an acquired hernia there is no neck to the sac, the mouth opening directly into the body. Apart from their difference in origin the distinction between a typically acquired and a typically congenital sac is abundantly clear. In an ordinary inguinal hernia as seen in the adult the general conformation of the sac very closely resembles that of a congenital hernia and differs in many important particulars from the sac of an acquired hernia, yet curiously enough it is regarded by almost all surgeons who have written on this subject as having been acquired.

During the last few years I have operated upon a number of infants and older children for the radical cure of inguinal hernia and the experience thus obtained has greatly shaken my faith in the orthodox surgical belief. I have found that in the child, and even in the infant, the sac is in the vast majority of cases entirely separate from the tunica vaginalis and, apart from its delicacy in structure, exactly resembles that found in the ordinary hernia of the adult.

A few months ago I operated on the same afternoon upon a man, 45 years of age, and upon an infant, two months of age, for the radical cure of inguinal hernia. The general appearance and arrangement of the sac were identical in each and yet in the case of the infant it can hardly be disputed that the bowel had descended into a pre-formed sac. Two years ago a young man was admitted to hospital on account of a strangulated inguinal hernia. He had never been ruptured before and the hernia had appeared suddenly whilst he was lifting a heavy piece of timber. I saw him shortly after his admission and operated within five hours of

the accident. The hernia was scrotal, the sac being extremely thin and unconnected with the tunica vaginalis. Apart from its thinness the sac exactly resembled that ordinarily met with, yet it is much more probable that the bowel had descended into a still patent portion of the processus vaginalis than that a sac of such a size and shape had been suddenly acquired. Last year I operated upon a man, 49 years of age, for the radical cure of an inguinal hernia which had first appeared nine years previously. The appearance which the sac presented was very interesting; it was completely shut off from the tunica vaginalis but was connected with it by a firm fibrous cord one inch in length and one-eighth of an inch in diameter, which was pervious for a short distance at the upper part. In this instance, though the hernia had not appeared until the age of 40 years, it is obvious that the bowel had descended into an obliterated portion of the processus vaginalis.

After some experience in operating for oblique inguinal hernia in infants, older children, and adults, I have been greatly struck by the marked resemblance as regards the shape, general appearance, and relationship of the sac. I have been quite unable to distinguish between a pre-formed and an acquired inguinal sac, for, I believe, the very good reason that they are one and the same thing. In many cases of ordinary inguinal hernia occurring in adult life the sac on dissection has shown undoubted evidence of its pre-formation. It is generally agreed that in infants and young children the sac of an inguinal hernia is usually pre-formed; and if my observations and those of others are correct—viz., that in adult life exactly the same kind of sac as that seen in the infant is the one usually met with, the inference is obvious; both have a common origin. In a person with a perfectly formed abdominal wall I believe it to be impossible for a hernia to occur.

It is well known that partial patency of the processus vaginalis may persist throughout life and I am anxious to know with what relative frequency this patency is found in the dead body of the adult quite apart from hernia, for the relative frequency with which this process remains patent during adult life forms the strongest or weakest point, as the case may be, in my line of argument. Unfortunately, I have been unable to discover any such statistics based upon a sufficiently large number of cases to prove the point. However, Mr. Macready, quoting from Professor F. C. Hesselbach, says: "At birth the serous canal is very often open on one or both sides, either totally or partially. At first it tends to close very rapidly, but after the third week more slowly. In adult life patency of the canal, which may be met with up to an advanced age, though not uncommon, is far rarer than in childhood and the calibre of the passage seems to be usually very narrow." To quote still further from Mr. Macready's work: "The size of the opening is, as a rule, larger on the right side than on the left and oftentimes the size is greater in older than in the younger children; and this last fact implies that the tendency to obliteration may remain in abeyance and that the growth of the canal may keep pace with the growth of the child. This observation is of some consequence, for it assists to explain the abundant production of ruptures as the age of puberty is reached. Though complete or partial patency of the processus vaginalis is regarded as an important predisposing cause of rupture, at all events those in early life; there can be no doubt, if the evidence from the examination of the dead be received, that hernia enters this passage in the minority of instances in which it remains open. If an unclosed canal was universally attended with rupture, the number of ruptures, as Engel remarked, would be very much greater than it is."

How then can we explain the fact that hernia occurs in some cases and not in others? Granted the existence of a potential hernial sac, I would suggest that the occurrence or not of a hernia largely depends upon two factors—the size of the opening at the internal abdominal ring and the strength of the muscles guarding it. It is unnecessary for me to enter into anatomical details as to the obliquity of the inguinal canal and the attachment of the internal oblique and transversalis muscles, which together with Poupart's and the ligament form a sphincter-like structure guarding the canal. Mr. Hamilton Russell has particularly emphasised this point. If in the case of patency of the processus vaginalis the opening at the internal abdominal ring be small and the muscles guarding it (which with some justice might be called the inguinal sphincter) powerful, then the probabilities of a hernia occurring are slight. If, on the

intravascular leucolysis takes place to any great extent in leukemia. At least, cytolytic changes in dried films have not been specially noted in the recorded cases but it is quite conceivable that in the lymphatic form of leukemia more particularly large numbers of lymphoid cells are destroyed in the circulating blood. From Halber and Linser's experiments these latter cells appear to be the most susceptible to x ray influence. Is the diminution of the leucocytes in the circulating blood to be attributed to increased destruction of cells in the hæmopoietic organs or to inhibited production? If increased destruction is the cause one might expect to find evidence of this in the uric acid output. During the five months preceding the adoption of x ray treatment in our case frequent analyses of the uric acid output were made with a view to determine whether according to Horbaczewski's theory any relationship could be found between the purin output and the leucocyte count. At the same time estimations were made of the total nitrogen and total phosphoric acid. Before commencing these investigations it was anticipated that a stage in the progress of the disease might supervene in which the leucocytes might show a progressive tendency to diminish, so that one might definitely demonstrate whether a simultaneous rise in the uric acid took place as the result of leucocyte destruction. As already noted, however, no progressive diminution took place in the leucocyte count during these five months, although marked oscillations were frequent. As has been so frequently noted in leukemia, the absolute amount of uric acid excreted was found to be much in excess of the normal but it was impossible to demonstrate constantly any rise in the uric acid as the immediate result of a temporary fall of the leucocytes lasting, perhaps, one or two days. Nor could any clue as to the occurrence of leucocyte destruction be obtained from the amount of phosphoric acid excreted. This was slightly higher than normal but it bore the usual proportion to the total nitrogen excreted.

When the leucocytes were progressively falling under x ray influence a further short series of urinary analyses was made. It was found that the total amount of urine passed per day had slightly increased. The total nitrogen and total uric acid were both relatively high but the percentage of uric acid nitrogen in the total nitrogen remained only slightly affected. The phosphoric acid output was also relatively high but its proportion to the total nitrogen remained as before. It may therefore be assumed that the fall of the leucocytes in our case was not the result of increased destruction but more probably of diminished production.

During the last few months brief reports of urinary analyses in the course of the x ray treatment of leukemia have been recorded. Rosenberger¹¹ found a diminution in the uric acid while the leucocytes were falling. Sohleip and Hildebrandt¹² found that the variations in the amount of uric acid passed were so great that no conclusions could be drawn. Strümpell,¹³ Jocchim and Kurpijewitz,¹⁴ and Loessen and Morawitz¹⁵ (in one fatal case) demonstrated an increase in the uric acid while the leucocytes were falling. The bulk of the chemical evidence, however, is in favour of the view that the x rays exert an inhibitory action on the hæmopoietic organs. What effects do the rays produce on the leucocytes and uric acid output of healthy persons? In this connexion Bloch¹⁶ has recently reported a rise of the uric acid with a fall of the leucocytes in a case of chronic eczema exposed to the x rays. As this is merely an isolated observation it would not be desirable to draw any definite inferences at this stage. The subject demands further investigation. I shall now record briefly the post-mortem and histological findings in our case.

Both the lungs were much congested and in the right lung were several patches of catarrhal pneumonia. Both liver and spleen were enormously enlarged, the latter organ weighing 7½ pounds. The lymphatic glands on each side of the spine, both in the abdomen and thorax, were also enlarged and varied in size from that of a pea to that of a large bean. The bone marrow, as seen in the sternum, vertebrae, and ribs, had a pale pink colour. Without entering into

detail it will be sufficient here to note the more important changes in the blood-forming organs.

Spleen.—Malpighian follicles were practically absent. There was a marked development of coarse connective tissue pervading the spleen pulp but this fibrotic process had not advanced to the degree which one generally finds in chronic cases of spleno-medullary leukemia. The predominant cellular constituents of the pulp were large, mononuclear cells with intensely basophile protoplasm. Their nuclei were round or oval and slightly vesicular. In their morphology they resembled the basophile myelocytes of Dominici. Numerous mitotic figures in all stages were seen in these cells. Fully developed cells of the neutrophile series were very scarce.

Lymph gland.—No nodes were visible. Large basophile cells were here also predominant but there were also enormous numbers of giant cells mostly of the megakaryocyte type. Here and there were noted small groups of cells with ill-defined contours containing in their interior two or three densely stained half-moon-shaped bodies. It is probable that these cells represent degenerated megakaryocytes but it is difficult to explain how the broken-down nuclei should assume such regular semicircular forms.

Marrow from the sternum and ribs.—So far as its cellular constituents were concerned the marrow might be said to be in a markedly hypoplastic condition. Bony lamellæ and strands of connective tissue traverse the section, leaving small isolated cellular areas. Small or large lymphocytes were most numerous. Large basophile cells were scarce and giant cells were not nearly so numerous as in the lymph glands. Nucleated red cells were also very scarce.

Liver.—The interacinar capillaries were quite choked with leucocytes, the great majority of which consisted of the large basophile cells met with in the spleen and glands.

Can we bring these changes into line with those met with in the hæmopoietic organs of experimental animals that have been exposed to the x rays? The absence of Malpighian follicles in the spleen is a common feature in chronic spleno-medullary leukemia and hence cannot be regarded *per se* as the result of radio-therapy. The great scarcity of lymphoid elements in the spleen pulp is certainly a conspicuous feature but the most remarkable change is the substitution of proliferating undifferentiated basophile myelocytes for the fully formed neutrophile elements which one usually finds in the spleen of chronic spleno-medullary leukemia. In cases of acute leukemia these cells have been found in active proliferation in the bone marrow, spleen, and lymph glands (*vide* Aubertin¹⁶) and one might presume that the real cause of death was an attack of acute leukemia superposed on the chronic form during the leucopenic stage. The condition, however, permits of another, and to me more probable, explanation. During the first series of x ray séances the percentage of cells of the neutrophile series rose (the increase affecting the polynuclear elements), while the lymphocyte percentage fell. After the suspension of the rays in August the lymphocyte percentage began again to mount upwards. On the resumption of the x ray treatment in December the neutrophile percentage rose markedly while the lymphocyte percentage fell, but the change was only transitory. When the total leucocyte count was approaching normal limits the polynuclear percentage fell markedly while the lymphocyte percentage rose. So long as a relatively high leucocyte count obtained, the main effect of the x rays would be on the lymphocyte series, as Heineke noted. Now, from the histological appearances it would seem that the spleen and lymph glands were the hæmopoietic organs most actively functioning. Thus, in spite of the inhibitory action of the rays on the myeloid function of the spleen there would result, owing to the destruction of the more susceptible lymphocytes, a relative increase of fully formed polynuclear cells in the circulating blood. When, however, the leucopenic stage intervened during the second series of séances, the ever-increasing tendency to diminished production must have considerably curtailed the myeloid function of the spleen or its power of sending forth into the circulation more or less fully formed neutrophile cells. Moreover, what one might call the Mosè and Michner effect already referred to would come into play. Hence the presence in such numbers of these basophile-indifferent cells in the spleen and glands, accompanied by a diminution in the fully formed neutrophile cells of the circulating blood, might not be so unexpected a

every hour by the mouth with the addition of ten minims of brandy in each spoonful of water. At 9.30 P.M. the woman was comfortable and free from pain. There had been no more vomiting and the bowels had not acted again. The temperature was 100° and the pulse was 100.

At 3.30 A.M. on Saturday I was sent for again. The woman had become much worse, had vomited repeatedly, complained of intense abdominal pain, and become much collapsed. She was clearly in *extremis*; the temperature was 98°, the pulse was 140, but the abdomen was not rigid or distended. There was slight tenderness on the left side of the uterus. The tongue was clean and moist. There was no dulness in the flanks. Hot-water bottles were applied to the abdomen and a quarter of a grain of morphine tartrate and ½ of a grain of strychnine-hydrochloride were given hypodermically. The patient never rallied and death occurred at 5 A.M.

Post mortem there was about an ounce of blood-stained serum in the pericardium and in each pleural cavity. The lungs, heart, brain, spleen, liver, and kidneys were healthy. The small intestine was hyperæmic in places. Round the left ovary and in Douglas's pouch and in the lesser sac of the peritoneum was some flaky lymph. The stomach, pancreas and duodenum, and the appendix were healthy. There were several old adhesions round the left ovary and Fallopian tube, both of which were deeply congested. A drop of thick yellow pus was escaping from the left Fallopian tube, which contained about half a drachm more of the same material. The interior of the uterus was quite healthy. I could obtain no history of any symptoms of salpingo-oophoritis from any of the relatives.

The baby, having been taken out of the mother's room on Friday morning, was put to sleep on a cushion in an armchair in the kitchen. He was seen at 1 P.M. and was then all right, but at 2.30 P.M. he was found dead. A post-mortem examination showed that death was due to suffocation.

Weybridge.

HÆMATOLOGICAL AND CHEMICAL OBSERVATIONS IN A CASE OF SPLENO-MEDULLARY LEUKÆMIA UNDER X RAY TREATMENT,

WITH AN ACCOUNT OF THE HISTOLOGY OF THE HÆMOPOIETIC ORGANS AFTER DEATH.

By J. C. G. LEDINGHAM, M.B., B.Sc., M.A. ABERD.,
- LISTER INSTITUTE OF PREVENTIVE MEDICINE ELSTREE.

(From the Bacteriological Departments of the University of Aberdeen and London Hospital.)

At a laboratory meeting of the Pathological Society of London held at Claybury in July last a paper under the above title was read by me and will appear in due course in the published Transactions of the society. In view of the fact, however, that a preliminary communication on the same case was made to THE LANCET in January, 1905,¹ I propose here to record briefly the main results obtained during the latter history of the case.

The first series of x ray sèances lasted from May 17th to August 8th, 1904, and at the end of that time the patient's general condition had enormously improved while the changes in the blood picture were most striking. The white cells fell from an average of 200,000 to an average of 20,000 per cubic millimetre in the course of six weeks and there was also a very appreciable rise of the red cells in the same time. The red cell maximum was not reached, however, till the middle of August when the white cells were already mounting slowly upwards after the suspension of the x rays. Arneth² in a recent paper has also noted this late response on the part of the red cells to x ray influence. During September, October, and November, 1904, the patient remained in a convalescent home where he enjoyed excellent health. Frequent blood examinations were made during this time and it was found that the white cells were rising very gradually and in a somewhat irregular fashion. At the end of November a level of 60,000 had been reached. It is

an exceedingly suggestive fact that the suspension of radiotherapy for three months did little more than raise the total count of the white cells to one-third only of their numbers at the commencement of the treatment. It certainly shows that the radio-therapy had exerted an inhibitory influence on the proliferative functions of the blood-forming organs.

After the patient's return to hospital a second series of x ray sèances was commenced on Dec. 1st, 1904, and again there was a remarkable response on the part of the blood elements. The white cells fell progressively in the course of six weeks to the normal, or rather subnormal, level of 7000. When this low level had been reached the question of the advisability of continuing the x ray treatment was raised, the risk being that the circulating blood might be completely depleted of leucocytes, and in the light of the recent animal experiments of Halber and Linser³ to which I shall refer later, this fear would have been perfectly justified. However, no such effect took place. This low level proved again to be a position of unstable equilibrium and the white cells rose very slowly to a level of 12,000. It is impossible to say whether the white cells could have been retained for an indefinite period within normal limits, owing to the unfortunate intervention of an influenza attack leading to the fatal conclusion. On Feb. 24th the temperature, which hitherto had run a consistently normal or subnormal course, rose to 101° F. This heralded an attack of bronchitis during which the temperature rose on one occasion to 102° 5°. The clinical symptoms were not, however, very pronounced and the end came rather unexpectedly on March 8th—i.e., 14 days after the commencement of the intercurrent affection. One count only was made during the fatal illness and the white cells were found to have mounted up to 43,000. The leukæmic leucocytes had in fact reacted to the intercurrent affection somewhat more vigorously than normal leucocytes would but in the same direction. Now it is a well-established fact that intercurrent affections in leukæmia produce a great fall in the number of leucocytes but here in the leucopenic stage of leukæmia the reaction was in the opposite direction.

A necropsy was fortunately obtained and I am indebted to Dr. G. M. Duncan of the Pathological Department, University of Aberdeen, for notes of the necropsy and for the tissues which were kindly forwarded to me for microscopical examination. The opportunity was thus afforded me of comparing the organic lesions with those described by Heineke⁴ Mosse and Milchner,⁵ Halber and Linser,⁶ and others in experiments on animals. Heineke found that the exposure of small animals such as mice to the x rays produced a destruction of the lymphoid follicles in the spleen and lymph glands. The nuclear detritus was taken up by phagocytes and the node was replaced by connective tissue and epithelioid cells. Prolonged exposure was followed by partial destruction of the granular cells of the marrow. Mosse and Milchner showed that in animals exposed to the x rays the bone marrow is profoundly influenced. The changes affect principally the cells of the neutrophile series which are greatly diminished in numbers, the surviving cells exhibiting great deficiency of granules. The experiments of Halber and Linser are even more remarkable. By prolonged exposure of small animals to the x rays they were able to deplete the circulating blood entirely of leucocytes (as measured by ordinary counting methods). The larger the animal the more difficult it was to free the blood of leucocytes and frequently in rabbits and dogs it was impossible to get lower counts than 1500 or 2000 by continued exposure. They maintained from examination of films that the destruction of leucocytes took place in the general circulation and not in the blood-forming organs. Further, fatal results sometimes ensued which they attributed to the evil effects of leucotoxins set free from the broken-down leucocytes. The serum of x-rayed animals had also the power of causing the destruction of leucocytes when injected into fresh animals. The question as to whether a destruction of leucocytes takes place in the general circulation is an important one. Most observers, with the exception of Grawitz,⁷ Aubertin and Beaujard,⁸ Weil and Aubertin,⁹ are inclined to doubt that

Dr. F. M. Sandwith, in an article on bilharziosis,¹ points out that there are three possible routes by which the miracidium or embryo trematode may arrive at its destination: (1) by the mouth; (2) by the skin; and (3) by the urethra or rectum. Of the above, Dr. Sandwith thinks the mouth is the most probable.

1. People who do not bathe in the rivers, ponds, &c., and who do not drink water which has not been boiled, can live

FIG. 1.

Magnified 65 diameters. Shows ova in clumps just outside the muscularis mucosae, and two internal to it.

in the countries in which this disease is endemic (e.g., Egypt, South Africa, Syria, &c.) and seldom contract it. Against this theory may be urged that: (a) bilharzia eggs or embryos have never been discovered in any molluscs or other articles of diet—in fact, the intermediate host of the bilharzia is unknown, if, indeed, there be one; and (b) that the embryo or miracidium which usually hatches in about half an hour after the ovum is voided in the urine is quickly killed if it is placed in an acid solution of equal strength to the gastric juice.

FIG. 2.

Magnified 110 diameters. Two ova just outside muscularis mucosae.

2. Infection by the skin. Dr. John Harley, who first discovered bilharzia in South Africa in 1854, supported this view. I do not know of any other evidence in the favour of it except, if we may judge from analogy, ankylostomum duodenale has lately been shown to attack its host in this manner.

3. The third possible means of entry is by the urethra or less often by the rectum.

Dr. Sandwith states that in the Cairo hospitals the proportion of males to females suffering with this disease is 24 males to one female; and also that when females are attacked it is often the vagina alone that is affected. There is also a good deal of evidence in favour of the disease being contracted when bathing. The only place in the human body where the bilharzia has been found sexually active is in the portal veins; it would be easier for the embryos to get into the portal system from the urethra or rectum than from the mouth, where they would have to traverse the acid gastric juice.

In the case which I am describing we unfortunately only found the bilharzia ova in the appendix after the patient had left the hospital and was on his way to South Africa, so no special search for bilharziosis could be undertaken. However, the patient had incidentally said that he had frequently bathed since he had had the sinus in his back.

From the above facts I conclude that the patient first had an attack of appendicitis, which eventually left him with a sinus, leading to an abscess cavity, in close connexion with the proximal part of his appendix, and that afterwards the sinus was the means of entry of the bilharzia while he was bathing. This is, I think, a more probable explanation than that the original appendicitis was due to bilharzia infection.

On looking through the recent literature on the subject, I have been unable to find any account of a case of primary infection of the vermiform appendix with bilharzia. Dr. H. A. Kelly, in his treatise on the appendix, mentions cases in which each of the common parasitic worms that are found in the human body, including ascaris lumbricoides, tape-worms, and echinococcus, was found in the appendix. Thread-worms are not by any means so rare as the above, especially in children. Dr. Kelly also mentions that Aireton had a case of bilharzia of the appendix. I have been unsuccessful in tracing this further as no reference is given. Mr. F. R. S. Milton, surgeon to the Kasr el-Ainy Hospital, Cairo, in a series of lectures on the Surgery of Bilharziosis² does not mention any case in which the appendix was the seat of infection. Mr. Milton, however, reports a case in which the only manifestation of the disease was a sinus leading from the buttock to the sacrum. How far the case is analogous to the one now recorded it is impossible to say.

PATHOLOGICAL REPORT BY MR. SHAW.

Macroscopic.—The specimen is that of a vermiform appendix about two inches in length; it is about one-third of an inch in diameter; its peritoneal and muscular coats are torn in places, exposing the mucous membrane, and its peritoneal surface is discoloured and covered by old adhesions. A piece was cut out from each end after being hardened in Müller's fluid and microscopic sections were prepared.

Microscopic examination.—(a) *Proximal end.*—The lumen of the appendix is small and contains numbers of cast-off epithelial cells and leucocytes embedded in mucus, the lining epithelium is intact, and the glands of the mucous membrane are very numerous. A few nodules of lymphoid tissue are present. Outside this the submucous layer contains large numbers of wide lymphatic spaces. The muscular coats are of normal thickness and are deficient in places, having been torn during the removal of the appendix. The peritoneal coat is irregularly thickened and contains many small round cells; blood-vessels are numerous and large. There are collections of small round cells in all the coats of the appendix and dilated lymphatic vessels full of leucocytes are also seen. The evidences of inflammation are present mostly in the outer part of the wall of the tube. In the submucous coat immediately outside the muscularis mucosae there are numbers of darkly-stained bodies grouped together in some places in colonies of from four to eight in number; some are lying singly and some in pairs. The bodies are darkly stained with hematoxylin and lie in the connective tissue spaces. Seen in their long diameter they are about 0.1 millimetre in length and are oval in shape, some with rounded ends, others with tapering extremities, others again have one end rounded and the other prolonged to a sharp point. In several instances there is seen a kind of blunt spine on one side. On cross section the bodies are round. With the low power (Leitz's 3) a definite envelope can be made out and inside this there is in some of the bodies a mass of broken-up structureless material, while in others there are

¹ Practitioner, October, 1904.

² Journal of Tropical Medicine, June and July, 1922.

phenomenon. Whether such a spleen would serve the organism more beneficially than a more fully developed myeloid organ is difficult to decide. Most probably it would not, as undoubtedly the needs of the body would be better served by an organ whose power of manufacturing and sending into the blood stream an excess of fully developed neutrophile cells was well maintained.

The above considerations lead me to think that in the interests of the patient it would be advisable to exercise the greatest caution in continuing x ray treatment once the total leucocytes have attained normal limits. This is all the more necessary when one remembers the startling results of Halber and Linser's experiments which, though still lacking confirmation, suggest to us the greatest circumspection in the employment of radio-therapy under the conditions indicated; indeed, in the very few recorded cases of leukaemia which have ended fatally during or after x ray treatment the effects of leucotoxic products or liberated ferments have been assigned as exciting causes. As yet the only fatal case in which an accurate histological examination of the organs has been made is that recorded by Lørsen and Morawitz. Krause¹⁷ reported shortly in one case that it was impossible to demonstrate in the hæmopoietic organs changes which are not usually associated with leukaemia, and Lommel¹⁸ who examined the spleen in a case of pseudo-leukaemia which had been exposed to the rays, noted that the organ was very poor in lymphocytes.

Lørsen and Morawitz's case did not respond satisfactorily to the x rays. The leucocytes were profoundly influenced but the general condition did not improve. The histological changes they reported were briefly as follows. The spleen pulp showed a great scarcity of leucocytes, especially of myelocytes and lymphocytes. Fibroblasts were numerous. The lymph glands were also greatly deficient in lymphatic elements. The marrow especially showed great hypoplasia with regard to its myeloid and lymphatic elements. The interstitial tissue of the marrow was also increased. As a result of their findings the authors believe that in certain cases the x rays may give rise to a recognisable hypoplasia of the blood-forming organs. No satisfactory explanation has yet been given of the enormous improvement which almost invariably occurs in the general condition of the patient under the x rays. It is at least difficult to bring it into relationship with the blood changes. Of course, on the assumption of Senn and Ahrens that the x rays inhibit the development of, or actually destroy, the hypothetical parasite of leukaemia (Löwit), this improvement in the general condition would find ready explanation.

Certain investigations (to be recorded elsewhere) which I have made on the rôle played by the leucocytes of spleno-medullary leukaemia in the process of phagocytosis of bacteria have shown that in the leukaemic serum the substance preparing the bacteria for ingestion by the phagocyte ("opsonin" of Wright and Douglas) is generally in normal amount as measured by normal leucocytes, while a very much lower index is obtained when measured by the patient's own phagocytes. The myelocytes have exceedingly feeble phagocytic power and hence any factor that increases the number of ripe polynuclears in the circulating blood must also render the normal supply of opsonin more available for purposes of efficient phagocytosis and removal of effete matter from the tissues. It may be noted that in chronic lymphatic leukaemia the conditions appear to be reversed. At least in the two cases which I had the opportunity of examining frequently the polynuclear leucocytes, though constituting only 2 or 3 per cent. of the total, had almost double the phagocytic power of leucocytes of healthy people. In these cases the true opsonic indices as measured with the patient's own serum and phagocytes were relatively high. In performing these tests staphylococci and tubercle bacilli were employed.

SEAMEN'S HOSPITAL, GREENWICH.—On Thursday, Feb. 15th, the members of the local branch of the British Medical Association are to visit the Seamen's Hospital, Greenwich, in connexion with the new post-graduate school which has just been established at that institution. The staff of the hospital wish it to be known that any medical man, whether belonging to the local branch or not, will be welcomed. There will be an exhibition of cases and it is intended to hold the meeting at about 4 P.M.

A CASE OF BILHARZIA INFECTION OF THE VERMIFORM APPENDIX.

By J. BURFIELD, M.B., B.S. LOND., F.R.O.S. ENG.,
RESIDENT ANÆSTHETIST, LATE HOUSE SURGEON, ST. BARTHOLOMEW'S HOSPITAL.

With a *Pathological Report* by ERNEST H. SHAW,
M.R.C.S. Eng., L.R.C.P. Lond.,
HOUSE SURGEON, ST. BARTHOLOMEW'S HOSPITAL.

THE patient, a well-developed but rather anæmic man, aged 36 years, was a goods clerk in a railway station in South Africa. He was admitted to St. Bartholomew's Hospital on June 24th, 1905, on account of a sinus in the right gluteal region. The sinus had persisted since January, 1904, when an abscess was opened there by Dr. J. B. S. Greathead at the Albany General Hospital, South Africa. He had come from South Africa to have the sinus cured. His history was as follows. In January, 1899, he had a slight attack of appendicitis which cleared up after rest in bed for ten days. In April, 1902, a large tender swelling developed in the right iliac region; he had fever and was constipated. He was sent to the Albany Central Hospital by Dr. E. G. D. Drury. At this time the swelling could be felt per rectum; it was painful and fluctuated. The pelvic swelling became smaller and the patient was discharged in six weeks without any operation being performed. But the swelling never entirely disappeared and the patient was very weak and unable to do any work till October, 1902, when the abscess pointed on the right lumbar region. Two incisions were made into this between the last rib and the iliac bone and some foul-smelling, dark brown pus was let out. In December, 1902, he was able to work again, wearing a drainage-tube in the sinus.

In January, 1904, another abscess developed in the upper part of the right gluteal region outside the posterior superior spine of the ilium and the patient was readmitted into the Albany Hospital. The appendix region was then explored by the usual oblique incision in the anterior abdominal wall. Dense adhesions were found and a fluctuating swelling was discovered behind the pelvic peritoneum in the region of the sciatic notch. The anterior incision was therefore closed. The abscess in the right buttock was opened up and its cavity was found to lead into the pelvis through the sciatic notch into an abscess in front of the sacrum, whence several ounces of dark faecal smelling pus were let out. This sinus was still discharging on the patient's admission to St. Bartholomew's Hospital under Mr. C. B. Lockwood in June, 1905. His condition was as follows. There was a scar about four inches long in the anterior abdominal wall, which was the seat of a ventral hernia. Behind there were four scars in the right lumbar and gluteal regions, in the lowest of which there was a sinus leading forwards and inwards for about four inches. The sciatic notch could be felt with a probe but the bone was not bare. There were resistance and tenderness in the right iliac fossa. The urine was natural and did not contain blood or pus cells although systematically examined.

On July 14th, as the sinus showed no signs of closing, Mr. Lockwood explored the appendix region through the scar in the anterior abdominal wall. After a long and tedious search, lasting over an hour on account of the dense adhesions, the proximal end of the appendix was found very firmly adherent to the posterior pelvic wall near the sciatic notch; this part of the appendix was removed. The distal end had apparently sloughed away. A small drainage-tube was left in and the abdominal wall was sutured in layers. The patient left the hospital five weeks after the operation; the abdominal wall had soundly healed. The posterior sinus was healing quickly and was only about one inch in length.

On cutting sections of the appendix ova of bilharzia hæmatobia were seen; they are shown in the accompanying micro-photographs (Figs. 1 and 2). There was nothing to suggest bilharzia infection of the genito-urinary tract or of the rectum; the patient never had diarrhoea and no blood or mucus was ever seen in his stools. Apart from the extreme rarity of bilharzia infection of the appendix, this case is instructive because it throws some light on the way by which the parasite may enter its host.

Dr. F. M. Sandwith in an article on typhus fever points out that there are three possible routes by which the typhus fever or enteric fever may arise at its destination: (1) by the mouth; (2) by the skin; and (3) by the system or system. Of the above, Dr. Sandwith thinks the mouth is the most probable.

1. People who do not bathe in the stream, ponds, &c., and who do not drink water which has not been boiled, can live

FIG. 1.

Micrograph of specimen. Shows several small, dark, oval-shaped structures, likely typhus fever or enteric fever, embedded in a lighter, granular matrix.

in the countries in which this disease is endemic (e.g., Egypt, South Africa, Syria, &c.) and seldom common in England this theory may be ruled out: (a) typhus fever or enteric fever have never been discovered in any material or other studies of the—In fact, the immediate host of the typhus is unknown, it indeed, there be one; and (b) that the typhus or enteric fever which usually attacks in about half an hour after the victim is killed in one minute is quickly killed if it is placed in a weak solution of equal strength to the gastric juice.

FIG. 2.

Micrograph of specimen. Shows a large, dark, oval-shaped structure, likely typhus fever or enteric fever, embedded in a lighter, granular matrix.

2. Infection by the skin. Dr. J. H. Huxley, who has observed typhus fever in South Africa in 1881, suggested this view. I do not know of any other evidence in the favor of it except that it is very rare from Africa, and typhus fever has been shown to attack the host in the manner.

3. The third possible means of entry is by the system or system of the system.

—F. BUEFIELD, Oct. 1905.

Dr. Sandwith states that in the Oude hospital the proportion of males to females suffering with this disease is 21 males to one female; and also that when females are attacked it is often the vagina alone that is affected. There is also a good deal of evidence in favor of the disease being contracted when bathing. The only place in the human body where the typhus has been found usually active is in the nasal cavity; it would be easier for the typhus to get into the nasal system from the system or system than from the mouth, where they would have to traverse the acid gastric juice.

In the case which I am describing we unfortunately only found the typhus one in the appendix after the patient had left the hospital and was on his way to South Africa, so no special search for typhus could be undertaken. However, the patient had incidentally said that he had frequently bathed since he had had the fever in his back.

From the above facts I conclude that the patient first had an attack of appendicitis which eventually left him with a sinus, leading to an abscess cavity, in close connection with the peritoneal part of his appendix and that afterwards the sinus was the means of entry of the typhus while he was bathing. This is I think a more probable explanation than that the original appendicitis was due to typhus infection.

On looking through the recent literature on the subject I have been unable to find any account of a case of primary infection of the typhus appendix with typhus. Dr. H. A. Kelly, in his treatise on the typhus, mentions cases in which each of the common typhus forms that are found in the human body, including typhus, typhoid, enteric, and enteric, was found in the appendix. These forms are not by any means so rare as the above especially in children. Dr. Kelly also mentions that there had a case of typhus of the appendix. I have been unsuccessful in making this further reference to given. Dr. B. D. S. Wilson, surgeon to the Glasgow Hospital, Glasgow, in a series of lectures on the surgery of typhus, does not mention any case in which the typhus was the seat of infection. Mr. Wilson, however, reports a case in which the only manifestation of the disease was a sinus leading from the trunk to the stomach. How far the case is analogous to the one now recorded it is impossible to say.

PATHOLOGICAL EXAMINATIONS BY MR. SHAW.

Macroscopic.—The specimen is that of a typhus appendix about two inches in length; it is about one-third of an inch in diameter; its peritoneal and muscular coats are torn in places, exposing the mucous membrane, and the peritoneal surface is discolored and covered by old adhesions. A piece was cut out from each end after being fastened in Muller's fluid and microscopic sections were prepared.

Microscopic examination.—(a) *Proximal end.*—The inner of the appendix is small and contains numbers of ciliated epithelial cells and leucocytes embedded in mucus, the lining epithelium is intact, and the glands of the mucous membrane are very numerous. A few colonies of typhoid virus are present. Outside the submucosa layer contains large numbers of white lymphatic corpuscles. The muscular coats are of normal thickness and are distinct in places, having been torn during the removal of the appendix. The peritoneal coat is irregularly thickened and contains many small round cells: these vessels are numerous and large. There are collections of small round cells in all the coats of the appendix and of small lymphatic vessels in all the coats. The vessels of the submucosa are swollen, many in the outer part of the wall of the tube. In the submucosa coat immediately outside the muscularis mucosae there are numbers of dark-stained bodies grouped together in some places in columns of four five or eight in number; some are lying singly and some in pairs. The bodies are dark stained with hematoxylin and lie in the connective tissue spaces. Seen in thinning sections they are about 0.5 microns in length and are oval in shape. Some with rounded ends, others with slightly emarginated ends, again have one end rounded and the other pointed to a sharp point. In several instances there is seen a halo of thin granular material. On cross section the bodies are round, with the lower part (darker) a definite envelope can be made out and inside this there is a core of the bodies a mass of granular material, while in others there are

collections of round granules about one-third of the size of a red blood corpuscle. Stained with methylene blue these granules are dark blue in colour, and around them and filling up the remainder of the envelope is a structureless hazy-looking mass lightly stained with blue. The envelope is also stained deeply blue. Some of the bodies are distorted and broken up and, from their staining reaction, give one the impression that they have undergone some degenerative change—i.e., calcareous degeneration. With the high power (Leitz's $\frac{1}{2}$) the granules and the definite chitinous-looking wall can be seen much better. A few of these bodies, which correspond exactly in size and shape to the ova of the bilharzia hæmatobia, and are no doubt the ova of that worm, are seen in the lymphoid tissue of the mucosa, and there are many in the peritoneal coat. None are seen in the lumen of the appendix, nor can any be seen in the muscular coats.

(b) *Distal end.*—The tissues show very little evidence of inflammation and there is no ulceration of the mucosa. But the ova are present in the same situations and in large numbers. This points to an invasion of the whole length of the wall of the appendix by the ova.

The accompanying illustrations, which were prepared by Mr. Albert Norman, show the general distribution and structure of the ova. Another section has since been made from about the middle of the tube and shows the same appearances with, in addition, a very interesting feature—that is, an ovum in a lymphoid nodule and partly surrounded by large multinucleated giant cells.

We are much indebted to Mr. Lockwood both for his kind help in the preparation of this article and also for his permission to publish it.

St. Bartholomew's Hospital.

A CASE OF TORSION OF THE TESTICLE.

By R. M. GOING, F.R.O.S. Eng.

With Notes on the Pathological Condition in Three Specimens by ARTHUR KEITH, M.D. Aberd., F.R.O.S. Eng.

THE patient, aged 17 years, was first seen on Sept. 11th, 1905, for pain and swelling of the left side of the scrotum. It was difficult to get a complete history as the lad was mentally deficient since birth. About four years previously he had a blow on his scrotum which became swollen; he was attended by a medical man who kept him in bed till the swelling had disappeared. Several times since then he complained of pain in his scrotum but not severe enough to cause him to lie up. For some months past his mother noticed that his gait had been different from what it was previously—namely, he walked with his thighs kept close together. On Sept. 9th he complained of pain in the left side of his scrotum after defæcation. On the 11th I first saw him. The left side of his scrotum was swollen; the skin over it was red and slightly oedematous; it was very tender and the swelling extended up as far as the external abdominal ring, but the spermatic cord could be distinctly felt above the swelling. His pulse and temperature were normal and he had no other symptoms. It appeared to me to be a case of acute orchitis but I could not find any satisfactory cause for it. On the 12th he was seen by my partner, Dr. F. H. Alexander, who found the local condition much the same. The patient, however, had vomited several times and complained of headache; his bowels had not acted since the 9th and there was difficulty in micturition. On the 13th I again saw him; the local signs were as before, though the swelling was somewhat larger and there was a bluish discolouration of the skin over the testicle. We came to the conclusion that the case was one of torsion of the testicle. On the 14th I made an incision over the swelling; the tissues were greatly oedematous and on exposing the tunica vaginalis it was found to be greatly enlarged and adherent to the surrounding tissues. On opening the tunica vaginalis, which was greatly thickened, a dark purple-coloured mass was seen in front, which afterwards was found to be the globus major of the epididymis, and behind it was the testicle of a fairly normal colour and not much enlarged. There was very little, if any, fluid in the tunica vaginalis. I then dissected the tunica vaginalis from the surrounding parts and having ligatured the cord with fine silk close to

the external abdominal ring excised it. A small drainage-tube was placed in the lower end of the scrotum through a small incision. The original wound was closed with silk-worm-gut sutures and dressed with cyanide gauze. The drainage-tube was removed in 48 hours and the wound healed by first intention, the patient being allowed up on the fourteenth day. Since then he has been quite well and walks normally.

The case is interesting from the following points. 1. The rarity of the condition, only two cases occurring at the London Hospital in the last six years. I can find very few recorded cases, the last one being by Mr. G. H. Edington in THE LANCET of June 25th, 1904, p. 1782. 2. Recurring attacks with apparent recovery for several years. 3. The difficulty of diagnosis with an incomplete history from orchitis. 4. The apparent confusion between this condition and that of torsion of the spermatic cord.

Notes by Dr. KEITH.—With the addition of Mr. Going's case there are now three specimens in the London Hospital Museum representing strangulation of the testicle caused by the twisting of an abnormally long and narrow testicular mesentery. The normal attachment of the testicle is shown in Fig. 4; the whole length of the posterior border of both testicle and epididymis is bound firmly by a mesentery containing much fibro-muscular tissue between its widely separated layers. It is impossible to conceive that the normal attachment of the testicle could become twisted so as to give rise to strangulation in any circumstances whatsoever. Mr. W. McAdam Eccles¹ and Mr. E. M. Corner² attribute the possibility of such a twisting to the presence of such an elongated mesentery as is frequently found in imperfectly descended testes and this explanation I believe to be right.

So far I have not used the term "mesorchium" because, strictly speaking, it should not be applied to the mesentery that binds the testicle and epididymis to the posterior wall of the tunica vaginalis; that attachment represents the common mesentery of the testicle and of the Wolffian body, out of which the epididymis is developed. At first the testicle and Wolffian body have each their mesentery, which even then, however, fuse at their bases to form a common mesentery, but in the normal course of development in the male these bodies approach each other and their independent mesenteries disappear. I would willingly overcome any scruples about the strict use of the term mesorchium and apply it to the mesentery that normally binds the testicle to the tunica vaginalis and cord were it not that Mr. Corner² has figured the occurrence of a true mesorchium (see Fig. 6), which binds the testicle to the epididymis and common mesentery, just as the mesovarium binds the ovary to the broad ligament. In the female the mesentery of the Wolffian body forms the mesosalpinx; the basal part of the broad ligament represents the common mesentery.

A search amongst comparative and embryological material has not brought to light any animal in which the male genital gland is attached by a long narrow mesentery such as occurs in the three cases figured in Figs. 1, 2, and 3. But there is certainly one error of development in these cases, a malformation or maldevelopment of the gubernaculum testis. In Fig. 5 it will be seen that the gubernaculum grows up not only within the posterior or caudal end of the common mesentery of the genital gland, but also within the mesenteries of the Wolffian body and mesorchium and seizes the globus minor of the epididymis and caudal or posterior pole of the testis. A remnant of the gubernaculum is seen in the adult testis in Fig. 4 (7). In none of the three cases of strangulation of the testicle due to twisting dealt with here was there any trace of the gubernaculum; it is evident in Figs. 1 and 2 that the gubernaculum had laid hold of, not the testis and epididymis, but of the vas deferens which is seen to make a loop on the tunica vaginalis; further, it is inconceivable that a gubernaculum could ever have reached the testicle through such attachments as are shown in Figs. 1, 2, and 3. It is probable that such genital glands are provided *ab initio* with abnormally long mesenteries and that the gubernaculum seizes the peritoneum near the mesenteric base, but the elongated, pedunculated form of the mesentery of the testicle in these cases is produced on the arrival of that organ at the internal abdominal ring. The

Swelling caused by the engorgement and thrombosis of the veins shown in Fig. 4. 3. Epididymis (globus major). 4. Mesentery of testicle, elongated so as to represent an intra-tunicate part of the cord in Figs. 1, 2, and 3. 5. The spermatic cord. 6. The vas deferens which makes a loop on the tunica vaginalis in Figs. 1 and 2. 7. Remnant of the gubernaculum in adult. 8. Gubernaculum of a seventh month fetus. The caudal pole of the gubernaculum is normally smooth and has no adhesions to the surrounding parts. In Fig. 1 the twisting has been undone and the testicle restored to the position which it probably occupied during health.

gubernaculum in such cases cannot exert its strength directly on the testis to pull it through the abdominal wall but indirectly by means of the peritoneum and during the exercise of its force an elongation and narrowing of the mesentery of the genital organ would probably be produced. In short, I regard these testes which undergo torsion as allied with those which do not descend. Both are testes in which there is a maldevelopment of the genital mesentery and of the gubernaculum. When such testicles do descend into the scrotum they do so at the expense of an undue elongation of their mesentery during their passage through the inguinal canal.

Recently Mr. J. W. Dowden⁴ has described several cases similar to those figured here; a case is also well described by Mr. Edington.⁵ Dr. Grünert⁶ gives the details of one case and a summary of 22 others. More recent additions to the continental literature will be found in the accounts given by Dr. Heinrich Mohr⁷ and Dr. Hugo Klinger.⁸ The left testicle is apparently more frequently the site of torsion than the right but as the side is not always given full statistics are not available. In the present cases two were on the right and one on the left side. The extent of the torsion varies; it is frequently 360°. The twist is commonly towards the mid-line of the body, the globus major of the epididymis turning inwards and downwards. The majority of cases occur at or just before puberty.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF PUERPERAL SEPSIS DUE TO THE BACILLUS COLI COMMUNIS.

BY A. KNYVETT GORDON, M.B. CANTAB.,
LECTURER ON INFECTIOUS DISEASES IN THE UNIVERSITY OF MANCHESTER.

THE patient, a primipara, was admitted to Monsall Hospital, Manchester, on Dec. 6th, 1905, as a case of puerperal sepsis. She had been confined on Nov. 29th, a midwife only having been in attendance. Apparently the labour was normal and of short duration. On the fifth day after confinement she is stated to have had a rigor and on the sixth day the temperature was 102° F. Notwithstanding this, a medical man was not called in until the seventh day, when he at once notified the case for removal to hospital. On admission, the patient was apparently moribund; she was almost entirely comatose and obviously was suffering from intense septicæmia; there were marked anæmia and extreme abdominal distension. The uterus reached to the level of the umbilicus and was soft and flabby. There was a slight amount of foetid purulent vaginal discharge. The leucocyte count was 10,731. The patient was anaesthetised at once and examined in the operating theatre; cultures were taken from the interior of the uterus. There was a small tear in the perineum and also a slight amount of laceration of the cervix. The uterus was dilated and its walls were extremely thin and friable. Beyond some undue roughness of the placental site and general endometritis nothing abnormal was found. The whole endometrium was carefully removed with a sharp curette down to the muscle and the raw surface was rubbed with undiluted iodoform. As the uterus did not show any signs of contraction after the curetting a douche at a temperature of 120° was administered, but this also produced no reaction. The uterus was packed with 10 per cent. iodoform gauze. 100 cubic centimetres of polyvalent antistreptococcal serum, prepared from puerperal cases only, were administered. On the next day the patient was markedly worse; the temperature was 105° and there was a rigor lasting for 20 minutes. In the cultures nothing whatever but bacillus coli communis was found. Accordingly

⁸ Hugo Klinger: Ibid., Band III., 1905, p. 353.

100 cubic centimetres of serum prepared from a horse which had been injected with five pure cultures of bacillus coli communis (all of which had been obtained from cases under my own observation) were administered. The effect was most marked; on the next day the temperature had fallen, to 100° and the patient was obviously much better; consciousness had returned and the tongue was cleaning, and she expressed a desire for solid food. From this point she made an uninterrupted recovery and was discharged from hospital on Jan. 10th, 1906. There was then no sign of pelvic inflammation and the uterus was freely moveable and of normal size. The patient was well and strong.

I have elsewhere pointed out that bacillus coli infection, apparently subsequently to, and not at the time of, delivery is more common than is perhaps usually supposed. In this case it was obvious that the midwife was responsible for the infection, and the length of the incubation period—four days—is in favour of infection having occurred by contact between dirty clothes and the unprotected external genitals subsequently to delivery, rather than from manual examinations at the time of birth.

I have recorded this case as I have never previously met with a case in which bacillus coli was the only organism found and in which the reaction to this serum was so well marked, though I have frequently given it, along with anti-streptococcic serum, to cases in which both organisms were present. In this case anti-streptococcic serum was administered empirically, as I thought it best not to wait for the result of the cultures. I should add that the patient's blood was examined bacteriologically before the operation, 20 cubic centimetres being abstracted from the basilic vein, but it was found to be sterile. Both sera were prepared by Dr. Dawson, the director of the Wellcome Physiological Research Laboratories.

Manchester.

ENLARGED GLANDS OF THE NECK SUCCESSFULLY TREATED BY THE X RAYS.

By MILWARD E. DOVASTON, M.R.O.S. ENG., L.S.A.

THE patient was a girl, 18 years of age, whom I first saw in September, 1904, giving a history of an attack of scarlet fever in May, 1900, followed in a few months by gradual swelling of the glands of the right side of the neck. After pursuing several methods of treatment an operation for removal was undertaken in 1902. Early in 1903 the glands on the left side of the neck became enlarged in the same manner as the right and remained so until she came to me. She then had a conglomerate mass of enlarged glands, varying in size from that of a walnut to that of a hen's egg, extending from the angle of the jaw on both sides and meeting under the chin. They were hard, elastic, and moveable and diminished in size from above downwards. On the right side of the neck were two downards. One eight inches long, horizontally and another five inches long vertically, where removal had been attempted. There was no history of tuberculous disease obtainable. Treatment with the x rays was begun on Sept. 26th, 1904, and continued until July, 1905. The exposures were given for the first two months four times a week, afterwards three times, and the last five months twice a week. The improvement was at first evident in the disappearance of the tissues binding the glands together, after which the individual glands became more definite. The glands themselves then gradually lessened and eventually disappeared, leaving a perfectly formed neck on either side which has remained so up to Feb. 1st, 1906.

THE ASSOCIATION OF MEDICAL DIPLOMATES OF SCOTLAND.—The annual dinner of this association will be held at the Trocadero Restaurant, London, W., on Feb. 23rd at 7 for 7.30 p.m. Mr. C. St. Aubyn-Farrer, the President, will occupy the chair. The President of the Royal College of Surgeons of England and the President of the Royal College of Surgeons of Edinburgh have signified their intention of being present. The honorary secretary of the dinner committee, Dr. E. N. Féré, 12, Northampton-square, London, E.C., will be pleased to give further particulars.

WESTMINSTER HOSPITAL.

A CASE PRESENTING THE SYMPTOMS OF GASTRIC ULCER WHICH FOLLOWED THE INGESTION OF AN IRRITANT.

(Under the care of Dr. R. G. HEBB.)

For the notes of the case we are indebted to Dr. Frederick W. Price, medical registrar.

A young woman, a housemaid, 21 years of age, was admitted to Westminster Hospital under the care of Dr. R. G. Hebb on Nov. 20th, 1905, complaining of pain in the stomach and vomiting of blood. On inquiry the following history was obtained. The patient had been subject to occasional attacks of bronchial catarrh until she reached the age of 14 years; otherwise she had always been healthy. 18 months before admission she sustained a sprain of the left wrist, for which she consulted a medical man, who prescribed an external application. Owing to a mistake the patient swallowed an ounce of the fluid three times a day for nearly two days. Immediately after taking the first dose a dry feeling in the throat was experienced, accompanied by a burning and prickling pain, and soon followed by a painful sense of constriction in the throat and gullet. Vomiting quickly supervened, the vomit being tinged with blood. The patient suffered from severe colicky pains in the abdomen which were worse on pressure. The muscles of the abdomen were tense and there was great thirst. These symptoms recurred after each dose of the irritant; the bowels became constipated and micturition was painful. The tongue was coated and the breath was offensive. The vomiting, abdominal pains, and constipation continued after the poison was stopped. The patient was kept in bed for a fortnight, at the end of which period there was considerable hæmatemesis. All the symptoms had completely disappeared in four weeks but a week later the patient "caught a cold" and began to suffer from a pain occupying a small area in the epigastrium, with accompanying tenderness. Later the pain became more diffuse and in a few weeks' time it spread to the interscapular region. Its character varied, sometimes being sharp and at other times of a boring character. It was constant but was much worse a few minutes after taking food. A few days after the pain commenced the patient began to vomit almost immediately after each meal. The vomit consisted of food almost unaltered and of several ounces of bright red blood on each occasion. The pain was entirely relieved after the act of vomiting. The patient was fed by the bowel for a week, but the pain, tenderness, and vomiting of food continued for some time longer. Strict dietetic treatment was enforced, a complete recovery from the symptoms was made, and the patient remained perfectly well until May, 1905, when a precisely similar attack returned and responded to treatment in six weeks. The patient remained free from stomach symptoms until three or four weeks before admission, when vomiting of food commenced, accompanied by epigastric pain and tenderness and hæmatemesis three days later. These symptoms continued until admission to hospital. Since the swallowing of the poison the menstrual periods have been irregular and the patient has occasionally suffered from metrorrhagia, dysmenorrhœa, and leucorrhœa.

On admission, the patient was found to be a well-nourished young woman and had a moderately good colour. There was a fair appetite, the teeth were in fairly good condition, and the tongue was slightly furred. She was at once put on to rectal feeding and the nausea and vomiting ceased, but about ten minutes after each injection there was a pain in the epigastrium, spreading to the back, which was much aggravated by movement. There ite and

localised tenderness in the epigastrium. There was no evidence of dilatation of the stomach or of enlargement of the liver. Nothing abnormal was discovered on physical examination of the heart or of the lungs. The urine was acid, had a specific gravity of 1020, contained a deposit of urates, and was free from albumin. The usual treatment of gastric ulcer was continued and the patient left the hospital on Dec. 2nd free from pain and much improved in general health.

Remarks by Dr. PRICE.—It seems clear that this was a case of gastric ulcer which was caused by, and followed soon after, the ingestion of an irritant. I am much indebted to the kindness of Dr. Hebb for being allowed to publish this case.

GOVERNMENT CIVIL HOSPITAL, HONG-KONG.

UNUSUAL CASE OF LIVER ABSCESS; DEATH.

(Under the care of Mr. J. BELL.)

THE patient, a Chinese, aged 49 years, was admitted to hospital on August 25th, 1905. He looked very wasted and stated that he had been ill for over a month with fever but no very definite account of his illness was obtainable. All the internal organs seemed healthy, save that the liver dulness was slightly increased downwards. The tongue was very dry and furred, the urine was normal, and the temperature was subnormal. There were a number of purpuric spots of various sizes all over the body. A blood count taken by Lieutenant R. M. Ranking, R.A.M.C., was normal. The patient continued in much the same condition for a few days, obviously getting weaker all the time, and on the fourth day his temperature from being subnormal suddenly rose to 104° F. in the evening. The purpuric spots increased in size and in number and slight diarrhoea supervened, the stools being acholic, but no amœbæ or tubercle bacilli were found microscopically. The tongue continued to get drier and more furred. On the sixth day he had a rigor with a rise of temperature to 104°. The liver was found to be increased downwards, but was not tender. An ill-defined swelling extended on the right side from the middle line to the mid-axillary line. This swelling had a peculiar emphysematous feeling heard as loud friction sounds by the stethoscope. Aspiration over the dull and resonant areas gave exit to air and a little blood. The blood count gave 14,000 white cells per cubic millimetre. Jaundice now came on which rapidly increased to the time of death, which occurred on Sept. 5th, 11 days after admission. Aspiration of the area of liver dulness was negative as to pus. On the day following the rigor the temperature was subnormal all day; it rose on the next day to 102° and then continued subnormal till the end.

Necropsy.—At the post-mortem examination all organs were healthy save the liver, which was increased in size, extending two fingers' breadth below the costal margin. In the right lobe was a large well-defined mass of about the size of a large orange, extending to within half an inch of the surface, the mass being composed of thick cheesy material. Behind this and continuous with it was a small abscess cavity of about one-eighth of the size of the mass. The lining membrane of the abscess and the cut surface of the mass teemed with living amœbæ. The large intestine was quite normal and showed no signs of old or recent dysentery.

Remarks by Mr. BELL.—This was a most puzzling case. The absence of amœbæ in the stools or of any history of dysentery negatived liver abscess, more especially as the liver was not much increased and no pain or tenderness was at any time present. The advent of the ill-defined swelling in the abdomen with emphysema suggested the possibility of an abscess due to ruptured duodenal ulcer, the abscess being shot off by adhesions. Nothing was found post mortem to account for this peculiar crackling which none of us had heard of or met with before. The ingestion of such a large abscess is most unusual, if not the first of its kind, and would have made it impossible to treat the case if it had been diagnosed as the pus was quite solid. Was this an attempt on the part of nature to cure the case? Presumably the amœbæ reached the liver without first attacking the large gut—a most interesting fact.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

The Bacteriostatic and Agglutinative Properties of the Serum of Goats inoculated with Typhoid Cells, etc.—The Fatty Change in the Liver produced by Ligature of the Hepatic Artery.—Immunisation between Bacillus Pertussis and Bacillus Pseudo-tuberculosis Rodentium.—Natural Occurrence of Weil's Disease in the Guinea-pig.—Streptococcal Malaria.

A LABORATORY meeting of this society was held on Feb. 6th at the Lister Institute, Dr. C. J. MARTIN being in the chair.

Dr. ALLAN MACFADYEN made a communication upon the Development of Agglutinins and Bacteriolyins in the blood of animals (goats) which had been treated with typhoid cell-juices. It was shown that the agglutinins did not stand in a quantitative relationship to the protective substances present in the blood. The agglutinins were not therefore a reliable index of the immunising value of an antityphoid serum.

Dr. F. A. BAINBRIDGE and Mr. J. B. LEATHES read a communication on the Effects of Obstructing the Blood-vessels supplying the Liver. They said that it was possible by the artificial injection of either the hepatic artery or the portal vein to inject the whole capillary network of the liver lobules. There was reason to believe, therefore, that the arterial blood supplied not only the connective-tissue elements but also the cellular elements of the liver. In cats, ligature of the hepatic artery and of all the visible arteries running to the liver in the gastro-hepatic omentum caused death within 24 hours. Ligature of the hepatic artery alone was not fatal. The ligature was followed by a great increase of fat in the lobules (as observed histologically). The fat was for the most part confined to the inner zone of the lobules and was most abundant in livers examined a day or two after the operation; it gradually decreased in amount and at the end of a month the liver again presented a normal appearance. Recovery was doubtless due to the opening up of anastomotic channels and to gradual restoration of the supply of arterial blood. Ligature of a branch of the portal vein supplying one lobe of the liver was followed by the destruction of many cells in the inner zone of the lobules and later by considerable atrophy of the lobules, associated with very definite fibrosis of the interlobular connective-tissue. There was at first some increase in the amount of fat present (microscopically), but the change was very slight in comparison with that produced by arterial obstruction. Chemical analysis of a lobe of the liver removed at the time of the operation and of the rest of the liver some days after the operation showed that the actual amount of fat was not increased after tying the hepatic artery. The increase of fat observed microscopically did not indicate a real increase of the fat present in the liver. It was improbable, therefore, that either fatty infiltration of the liver from without or true fatty degeneration of proteid had taken place. They suggested that the apparent increase of fat was the result of the autolysis of very complex molecules made up of a fatty body normally bound up with proteid or other bodies. During health these combined fats could be detected microscopically, but when the nutrition of the cells was impaired by lessening their supply of oxygen these complex bodies broke down to such an extent that the fat was set free and became recognisable by ordinary histological methods. The fat appeared in the centre of the lobule which received the smallest supply of oxygen. The fatty change in the liver in anaemia and other conditions of malnutrition might possibly be accounted for in the same way. That the oxygen supply was the essential factor was indicated by the absence of fatty change after ligature of a branch of the portal vein.

Dr. ALFRED T. MACCOWKEY made a communication to the effect that by inoculating guinea-pigs with repeated and increasing doses of the bacillus pseudo-tuberculosis rodentium (Pfeiffer) it was possible to protect them against a subsequent inoculation of virulent bacillus pestis. Of 17 guinea-pigs immunised with bacillus pseudo-tuberculosis rodentium (Pfeiffer) not one succumbed to an inoculation with virulent plague bacilli, while of 1 control eight died from plague.

Dr. J. E. LEDINGHAM recorded a case of Acute Infective Jaundice in the Guinea-pig. The pathological changes in the organs were similar to those described in fatal cases of acute infective jaundice (Weil's disease) in man and birds. From the liver a bacillus was isolated having the morphological, cultural, and pathogenic properties of organisms of the proteus group which were first isolated by Jaeger in cases of Weil's disease.

Mr. L. NOON showed specimens of *Sarcocystis Muris*, a sporozoan parasite described first by Miescher in 1843 and now classified with the sarcosporidia. Theobald Smith was the first to succeed in transmitting it experimentally from mouse to mouse by feeding with infected muscular tissue. Others had failed to infect man or carnivora with the allied parasites of sheep and swine. Smith had also followed its development within the striped muscle fibre, up to the mature stage when the Miescher's tube was found to contain crescentic sporozoites. The sporozoites corresponding to the gymnosporidia of other sarcosporidia showed in films stained with Giemsa's stain a nucleus with red chromatin network, and the protoplasm blue with many round dull red granules at one pole. No forms were found which resembled the ohamydospores of other sarcosporidia in having a cuticle and striated polar body. A second life-cycle was unknown. Laveran had obtained a toxic extract from the sarcocystis of sheep which killed rabbits in eight hours with symptoms of cholera. The attempt to repeat this with sarcocystis muris had failed so far. The investigation was being continued.

OPHTHALMOLOGICAL SOCIETY.

The Treatment of Detachment of the Retina.—Acute Edema of the Eyelids.—Septic Thrombosis of the Cavernous Sinus.—Bitemporal Hemianopsia.—Exhibition of Cases.

A MEETING of this society was held on Jan. 25th, Mr. PRIESTLEY SMITH, the President, being in the chair.

Dr. A. M. RAMSAY read a paper on the Treatment of Detachment of the Retina. The paper was based on a record of 50 consecutive cases of detachment of the retina treated in the Glasgow Ophthalmic Institution during the four years ending Oct. 31st, 1905. The active treatment consisted in subconjunctival injections of from five to 20 minims of 1 in 2000 bichloride of mercury with 8 per cent. chloride of sodium solution, the severe pain that always followed being mitigated by the addition of a few drops of 1 per cent. cocaine solution. The injection was repeated as often as might be necessary, at intervals of from four to six days, and if no decided improvement showed itself within a fortnight free diaphoresis was induced by the subcutaneous injection of from one-eighth to one-quarter of a grain of pilocarpine, this alternating with the subconjunctival injections. If the site and character of the detachment were deemed favourable the subretinal fluid was always evacuated by scleral puncture. The patient was kept prone in bed with his eyes bandaged and every effort was made to improve his general well-being by careful attention to diet and to the action of the bowels, kidneys, and skin. Marked chemosis of the conjunctiva was essential and when the reaction to the subconjunctival injections was absent or ill-marked from 1 to 2 per cent. of dionine was added to the bichloride and chloride of sodium solution. Of the 50 cases treated ten showed a decided improvement and 13 a moderate improvement, though of the former group five, and of the latter group two, relapsed at intervals, varying from two weeks to four years. The more recent the detachment the more favourable the prognosis but the pathological antecedents of the affected eye were more important than the duration of the condition. Failure was the rule in all cases marked by a seriously degenerated choroid, a pupil sluggish to mydriatics, a much diminished tension, and sluggish to separation. The method of treatment outlined was simple, applicable to all cases, and, so far as Dr. Ramsay's experience went, never did any harm.—Mr. H. E. JULER referred to some cases of Galizowski in which posterior sclerotomy produced striking results though he had not seen them repeated and quoted a case which emphasised the importance of determining between simple detachment and that accompanying a new growth.—Sir A. ORTCHETT welcomed such a candid and truthful exposition of the subject and in spite of conflicting results he was strongly disposed to attempt the treatment recommended by Dr.

Ramsay.—Mr. SIMEON SNELL referred to cases submitted to various methods of treatment, the best of which recovered after tapping, though the results generally were unfavourable.—Mr. H. SECKER WALKER found greater benefit from subconjunctival injections of cyanide of mercury than from any other mode of treatment.—The PRESIDENT said that in cases of old standing, associated with myopia, there was nothing to do. He recommended the recumbent position and pressure with puncture and the subconjunctival injections, but results varied. New growth might be diagnosed by enlarged vessels in the neighbourhood of the detachment and by means of transillumination.

Mr. SNELL related a case of Acute Edema of the Eyelids on both sides in a pork butcher, aged 48 years. The day before he had been dressing a pig and the gut, at a part which contained a lot of worms, burst over his face. Immediately irritation was felt and the lids commenced to swell. He was seen three hours later by his medical man when the condition was the same as it was 22 hours later. The eyelids on both sides were intensely oedematous, projecting as a large semi-translucent swelling, leaving only a chink between them. There was considerable chemosis of the conjunctiva. The next day it was learnt that the swelling had greatly subsided and 24 hours later had disappeared, only some redness of the conjunctiva remaining. Experiments with the worms subsequently caused no irritation in guinea-pigs.

Mr. SNELL also described a case of Septic Thrombosis of the Cavernous Sinus. On May 1st, 1895, a young medical practitioner pricked a small vesicle on the left side of the upper lip with a gold scarfspring which had been used previously to open an abscess and which was thought to be clean. On the next day there were redness and swelling and towards the evening the patient had to give up work and retire to bed. The following day the condition of the upper lip was worse and further progress was noted on the fourth day. On the fifth day the blush extended over the left cheek towards the orbit. On this side proptosis occurred with swelling of the conjunctiva and edema of the eyelids. Later, the right eye followed precisely the same course, the protrusion being even more marked. Interference with the movements of the eye was complete, only becoming so on the left side two days before death. There were also palsy of the right facial nerve and deafness on the right side. Another symptom was dulness with evidence of effusion on the right side of the chest. The patient died 14 days after the commencement of the attack, his mind having been unaffected throughout. Mr. Snell remarked that the initial lesion was clearly the condition of the lip which the medical attendants had considered to be a malignant facial carbuncle. No post-mortem examination was allowed.—Dr. D. J. WOOD cited three cases of a similar nature. Antitoxic serum appeared to be the best remedy.—Mr. J. H. FISHER stated that the great bulk of cases resulted from infection of the lateral sinus from otitis media, though occasionally this originated in the face. Treatment was very unsatisfactory as compared with jugular vein infection.

Dr. WOOD related a case of Bitemporal Hemianopsia. The patient, a man, aged 33 years, had suffered for more than a year with frontal headache, failing vision, and loss of memory. His better eye, the right, had become the worse, $V = \frac{1}{4}$ (—4 D.), the left $V = \frac{1}{16}$ (—15 D.), and he had bitemporal hemianopsia with contraction of field and loss of fixation point in the right. Mentally he was dull, repeated himself, and forgot what he was going to say and became annoyed, and there was marked delay in answering questions. The pupils were sluggish and patellar reflex was nearly absent. During 52 days' observation in hospital he steadily grew worse mentally so that it became impossible to keep him there on account of his foul language at night and filthy habits. His friends refused to let him go to an asylum, and, though he had ceased to recognise them or to talk rationally, took him home. After another 62 days, during which there was little change except that he contracted "influenza" and developed a bad cough, he suddenly sat up in bed and began to ask sensible questions—became, in fact, suddenly sane. He rapidly improved and when seen some months later was entirely recovered mentally. His right eye was divergent, quite blind, and exhibited optic atrophy. The left eye had improved ($V = \frac{1}{4}$) and his field was slightly larger. The left pupil was active, patellar reflexes were good, but he had no recollection of his sudden recovery was good, but he had no recollection of anything during the previous three and a half months. The case was thought to be one of cyst of the pituitary body,

which during a fit of coughing had ruptured through the attenuated bone into the pharynx or nasal cavities, though nothing of this sort was noticed by the friends and the patient himself was unconscious till the actual relief of pressure had occurred.

The following cases were shown:—

Mr. A. S. MORTON and Mr. G. COATS: A case of Subconjunctival Cysticercus.

Dr. R. E. BICKERTON: (1) Supposed Growth of Choroid; and (2) Anophthalmos.

Mr. L. V. CARGILL: Orbital Tumour.

LIVERPOOL MEDICAL INSTITUTION.

A Case of Haemorrhagic Pancreatitis.—Posterior Vertebral Tuberculosis.—Curies of the Atlas and Axis.—Cardiac Hypertrophy in Graves's Disease.—The X Ray Diagnosis of Renal and Ureteral Calculus.

A MEETING of this society was held on Feb. 1st, Mr. FRANK T. PAUL, the President, being in the chair.

Dr. F. W. BAKER YOUNG reported a case of Acute Haemorrhagic Pancreatitis. The patient was a man, aged 30 years, who was addicted to alcohol. He was taken ill while at work, walked home, a distance of 50 yards, and died within 45 minutes of the onset of symptoms. At the necropsy the body and tail of the pancreas were found to be enlarged and infiltrated with fluid blood; the head of the organ was also involved but not to the same extent. There were blood-stained fluid in the lesser sac of the peritoneum and an ecchymosis on the left kidney over the site of its relation with the body of the pancreas. No other lesion was found that could account for death. The following points were of special interest: (1) the rapid onset and rapid termination; (2) the patient's age; (3) absence of vomiting; (4) absence of pain; (5) the fluid state of the blood, no clots having been found even 48 hours after death; (6) the engorgement of the abdominal veins with fluid blood; and finally, the medico-legal aspect of the case—had the pancreas not been examined the cause of death could not have been stated.—Dr. WILLIAM CARTER drew attention to the similarity of the symptoms in death from irritant poisoning and from haemorrhagic pancreatitis respectively, quoting the following from Dr. A. J. Chalmers's monograph on "Pancreatitis in Ceylon": "Especially I desire to draw attention to the legal post-mortem form where no mention of the pancreas is to be found. I think that this should be rectified and that in all legal post-mortems careful note should be made of the condition of the pancreas."

Mr. R. W. MONSARRAT read a short paper on Posterior Vertebral Tuberculosis. After mentioning the primary seats of the disease as it has been found in the vertebral arches he related two cases. In the one the disease involved the transverse process, pedicle, and lamina in the dorsal region; in the other it was confined to the lamina of the fourth cervical vertebra on the left side. Both cases were complicated by abscess and the cervical case also exhibited paralytic phenomena beginning on the left side and subsequently extending to the right and involving the bladder function. The paralysis in the second case rapidly disappeared after laminectomy and the clearing out of a mass of granulation tissue from the spinal canal.

Dr. T. R. GLINN related a case of Curies of the Atlas and Axis with displacement of the atlas backwards in which recovery took place, the patient ultimately dying from internal hydrocephalus. The curies was associated with post-pharyngeal abscess and the condition being recognised, the patient, a girl, was placed on a bed raised at its upper end, her head being fixed by a bandage to a rail, and the body extended by a weight attached to the feet. All her limbs and the bladder became paralysed and respiration embarrassed. Atropine proved valuable in relieving respiratory trouble. After many weeks she recovered, the last symptoms, those pointing to descending lateral sclerosis, nearly passing away. She entered service and remained well for several weeks but was readmitted comatose. After death great distension of the lateral ventricles was found. The odontoid process had slipped backwards and upwards; the cord was compressed to the size of a goose quill; and the axis and atlas were partly destroyed and ankylosed together. The hydrocephalus was probably caused by the displaced odontoid process thrusting the

medulla upwards against the cerebellum and closing Magendie's foramen.

Dr. T. R. BRADSHAW showed a case of Cardiac Hypertrophy in Graves's Disease. The patient was a girl, aged 16 years, with Graves's disease incompletely developed. There had been palpitation and suffocative sensations for a year. The most prominent sign was hypertrophy of the right ventricle, for which none of the common causes were present. Lately, slight enlargement of the thyroid had become apparent. Dr. Bradshaw commented on the rarity of demonstrable cardiac hypertrophy in Graves's disease, a fact pointed out long ago by Trousseau.

Mr. C. THURSTAN HOLLAND read a paper on the X Ray Diagnosis of Renal and Ureteral Calculus. The paper was divided into three portions: the positive, doubtful, and negative evidence of calculi. Illustrative cases were cited and lantern slides were shown to prove the value of the positive and the difficulties of the doubtful diagnosis. The paper was based on a series of 76 cases, in 22 of which calculi were shown by the x rays. The value of the negative evidence was discussed and it was pointed out that too frequently reliance was placed on plates which were not good enough to warrant a negative opinion. If plates of the proper quality were obtained, then, and then only, was negative evidence to be relied on. The value of a pressure-tube apparatus in taking these radiographs was also dwelt upon.—The PRESIDENT referred to the valuable aid in diagnosing lesions of the kidney afforded by the urine separator and radiography. Liverpool was fortunate in possessing an exceptionally skilled specialist in each department as he had had many opportunities of testing, and though at first he had not been prepared to give an unqualified acceptance to the results obtained by these methods experience had assured him that in proper hands they were thoroughly trustworthy and of the utmost assistance.—Dr. J. HILL ABRAM said that one of Mr. Holland's cases was a man, aged 43 years, who had been sent to him for pain in the right hypochondrium and loin. There had never been any renal colic or hæmaturia and nothing could be detected by physical examination. On one occasion Dr. Abram had found a few pus cells in the urine. Mr. Holland's report was decisive and Mr. Rushton Parker successfully removed two stones from the kidney. It was an enormous gain to have had an advance in their methods which would enable physicians to recommend surgical interference with much lighter hearts than in the past.—Mr. W. THRELWALL THOMAS alluded to the great service which the x rays in Mr. Holland's hands had been to him in many cases of stone of the kidney—even in a case of a large kidney filled with pus and in a very stout patient—in confirming the diagnosis. He would in every case of suspected calculus call in an expert radiographer for confirmation.—The following gentlemen also took part in the discussion of the paper: Mr. RUSHTON PARKER, Dr. NATHAN RAW, Sir JAMES BARR, and Dr. T. WALBY.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Jan. 26th, Dr. J. Lindsay Steven, the President, being in the chair.—Professor Sarneca Gemmell showed a case of Pseudo-hypertrophic Paralysis in an adult. Weakness in the legs with dull pain in the calves and lumbar region began four years ago when the patient was 19 years of age. In nine months he was forced to give up work and under the orders of his medical adviser remained in bed for six months. He was then admitted to the Edinburgh Infirmary where he was treated by massage, electricity, and Turkish baths for 16 weeks. On dismissal he was sufficiently well to resume work for 15 months but the symptoms returned and by Oct. 21st, 1905, when he was admitted to the Glasgow Western Infirmary, a walk of 200 yards exhausted him. There was no trace of any similar disease in his family. His condition on admission was as follows: The deltoid, biceps, and triceps were prominent. The forearms were large. The scapulae projected. The infrascapulari were distinctly enlarged. Below there was distinct atrophy of the erectors spinae. The gluteal muscles were small and flabby. The thighs were straight and atrophic. The calves were large and firm and measured 15 inches. Tested individually the muscles of the body were greatly weakened. They all reacted to the faradic and galvanic currents but required a current rather stronger than normal. The knee-jerks were obtained with difficulty. Sensation and heat sense were unimpaired. The gait was of the waddling type and the head was ducked forwards and downwards with each step. When

rising he turned over on to his left side, raised himself on his knees, then on his toes and hands, and gained the erect position by climbing up his thighs. He had been treated with massage, exercise, and the high frequency current with great benefit.—Professor Gemmell also showed a case of Friedreich's Ataxy in a boy, aged 16 years. There was a history of injury to the head six years ago. After this his power of writing became defective and was now very unsteady. Walking had been unsteady for six months and now his hands were unsteady. His habitual posture was one of kyphosis. His gait was very unsteady. He reeled and elevated his feet too high and stamped them down heel first. He could not walk along a plank or stand with feet together and eyes shut. The tongue was tremulous. His speech was slurring but had no staccato element.—Professor R. Muir demonstrated four cases of Cirrhosis of the Liver with Primary Cancer. He said that the association was not casual but etiological. In cirrhosis there were a degeneration of liver cells from pressure and, as a reparative process, a hyperplasia of other liver cells. This hypertrophy appeared sometimes to precede the beginning of cancer and the cancer arose from liver cells, often at multiple foci, as if the compensatory proliferation had passed its usual bounds and developed into a cancerous growth. Clinically such cases sometimes were associated with a rapid and an extensive ascites from a growth of cancer cells obstructing the portal vein.—Dr. Renton showed: 1. A case of Coxa Vara after operation. He had removed a wedge of bone from the femur below the trochanter on each side. The bone was then fractured outwards and the legs were put up in a double long splint. After union there was a gain of two inches in length and the patient could sit down without crossing his legs. He could now draw up his legs freely. 2. A boy, aged ten years, who had Gastro-enterostomy performed for Stricture of the Pylorus. The stricture had resulted from an ulcer of the stomach after enteric fever. The ulcer had caused hemorrhage and great dilatation of the stomach and had led to emaciation. His weight on admission was 2 stones 13 pounds and was now 4 stones. 3. A case of Cholecystocolotomy where a large stone had been impacted in the common duct, causing contraction and fistula. He had joined the gall-bladder to the colon with a Murphy's button which was passed on the eighteenth day.—Dr. Beatson showed: 1. A patient with Bilateral Ankylosis of the Hip and Spastic Condition of the Muscles. The gait in this case had suggested coxa vara but this condition and congenital dislocation had been eliminated by skiagraph. Under an anæsthetic it was found that the ankylosis was complete; abduction and all movement in an extended position were entirely absent. The muscles of the thigh were hypertrophied and spastic. There was a history of injury 11 years ago. One brother had tuberculous disease of the hip and a sister had never been able to walk. Dr. Beatson regarded the condition as a rheumatic affection. 2. A case of Cicatricial Keloid: one of the size of a walnut in the shoulder which arose from an abrasion caused by friction of the patient's braces, another behind the ear following a burn, and a third in the lumbar region from an acne pustule. X ray treatment had not been successful.
